|--|----------|---|----------|
| A | | B | |
| Abbreviating Code Messages.....Mark R. Lamb..... | 253, 556 | Assessment Work on Placer Claims.....Paul J. Case.... | 354 |
| Accident and Employers' Liability Laws, Industrial..... | | Atkinson, A. S.....Electrical Mine-Pumps in Europe.... | 334 |
|David Ross..... | 716 | Ditto.....Gas Engines for Mining Purposes.... | 300 |
| Insurance and Mine.....G. W. Traer..... | 717 | Austin, L. S...Calculation of Blast-Furnace Charges.... | 723 |
| Account Numbers.....H. E. West..... | 34 | Ditto.....Present Conditions at the Garfield | |
| Accuracy in Assays and Analyses. James W. Howson.... | 329 | Smelting Works..... | 590 |
| In Surveying.....Lee Fraser..... | 332 | Ditto.....The Root Positive-Blast Blower.... | 432 |
| Acid and Basic Processes, Relative Merits of..... | 756 | Australian Kimberley Exist? Does an John Plummer.... | 93 |
| Regeneration of Cyanide Solutions, Tests on..... | | Averill, Mark R....Excess Ground in Mining Claims.... | 493 |
|R. P. Wheelock..... | 814 | | |
| Adair, Alfred.....Cyanide History..... | 421 | B | |
| Address, Commencement.....John Hays Hammond..... | 600 | Balldon, S. Rivers.....Free Settlement Method of | |
| Adsorption, Colloids and.....E. K. Soper..... | 626 | Separating Slime..... | 556 |
| Agency, The Prospectors' and Miners'.....Editorial.... | 741 | Bain, H. Foster.....Petroleum Fields of Illinois.... | 153 |
| Agitation, Brown Type of Laboratory...T. S. Lawlor.... | 197 | Ditto.....Tunnel Driving in Colorado.... | 743 |
| Alaska and the Geological Survey.....Editorial.... | 644 | Ballagh, J. C., and K. Iwai..... | |
| District, Innoko..... | 228 |Investigation of Ferro-Boron.... | 185 |
| Drilling in Alluvial Ground in.....T. A. Rickard.... | 558 | Ballinger, Richard A.....Public Lands and | |
| Fairbanks Gold Region..... | 156 | Needed Legislation..... | 748 |
| Haines District.....W. A. Scott..... | 198 | Bannock, Nevada.....Charles S. Thomas.... | 820 |
| Innoko District..... | 228 | Barbour, Percy E.....Calculation of Blast- | |
| Pelly, Ross, and Gravel Rivers in.....J. Keele.... | 66 | Furnace Charges..... | 664 |
| Perseverance Mine, Juneau, Alaska..... | | Barnes, Charles S.....Platoro, Colorado.... | 224 |
|Company Report..... | 603 | Battery Plates, Sealing and Sweating of Copper..... | |
| Surveys Now Under Way..... | 67 |Sydney F. Goddard.... | 368 |
| White River Copper Properties..... | | Bear River District.....W. W. Rush.... | 152 |
|Guy A. R. Lewington..... | 755 | Bement, A.....Record in Tunnel Driving.... | 722 |
| Yakutat Bay Region..... | 719 | Bingham Canyon, The Story of....H. W. MacFarren.... | 129 |
| Alaskan Coal Lands, Conservation and.....Editorial.... | 813 | Utah, Yampa Smelter.....Leroy A. Palmer.... | 225 |
| Railways.....Editorial.... | 439 | Bird, Frank A.....Assay of Cyanide Precipitate.... | 504 |
| Aliens' Rights in Mining Claims.....H. B. Kaeding.... | 353 | Blast, A Large..... | 738 |
| All-Sliming.....Huxley St. J. Brooks..... | 760 | Blower, The Root Positive.....L. S. Austin.... | 432 |
| Ditto.....Edgar A. Collins..... | 389 | Furnace Charges, Calculation of....L. S. Austin.... | 723 |
| Ditto.....E. M. Hamilton..... | 255 | Ditto.....Percy E. Barbour.... | 664 |
| Ditto.....P. R. Whitman..... | 388 | Blasting Deep Holes.....O. H. Packer.... | 328 |
| Alluvial Ground in Alaska, Drilling in...T. A. Rickard.... | 558 | Blatchley, R. S....Drilling for Oil in Eastern Illinois.... | 613 |
| Alsace-Lorraine, Minerals in..... | 533 | Ditto.....Pumping and Shipping Oil | |
| Amalgamating Plates, Dressing..... | 503 | in Eastern Illinois..... | 678 |
| Amalgamation Experiments, Pan..... | | Boston Consolidated Mining Company..... | 641 |
|H. O. Hofman and C. R. Hayward.... | 529 | Boston-Sunshine Mill.....G. W. Wood.... | 295 |
| Uses and Limitations of Electrolytic....J. H. Jory.... | 476 | Bowers, George.....Natamas 1500-Ton | |
| American Institute Meeting.....Editorial.... | 438 | Plant for Crushing Dredge-Tailing..... | 609 |
| Merchant Marine.....Theo. F. Van Wagenen.... | 858 | Braden, Eugene B.....Smelter Versus Oil Fume.... | 192 |
| Ditto.....W. C. Wynkoop..... | 761 | Braden, William R...Costs at the Braden Copper Mine.... | 759 |
| Mining Congress.....336, 404, 435, 539 | | Bradford, A. H., and Roy P. Curtis..... | |
| Ditto.....Editorial.... | 371, 407 | Dredging at Breckenridge, Colorado.... | 361 |
| Smelting & Refining.....Company Report.... | 163 | Breckenridge, Colorado, Dredging at..... | |
| Andean Placers..... | 61 |A. H. Bradford and Roy P. Curtis.... | 361 |
| Angles with a 30-ft. Tape, Deflecting.Rufus J. Foster.... | 587 | Brick, Sand-Lime..... | 500 |
| Ditto.....Lee Fraser..... | 470 | Brockunier, S. H.....The First Rock-Drill.... | 53 |
| Anti-Dredging Convention, Sacramento..B. S. Noyes.... | 150 | Broken Hill Proprietary.....Company Report.... | 673 |
| Ditto.....W. B. Winston..... | 149 | Broken Hill South Silver Mining Company..... | |
| Apex, A Vein and Its.....J. W. Finch..... | 525 |Company Report.... | 738 |
| Application of Steel to Mine Timbering..... | 462 | Brooks, Huxley St. J.....All-Sliming.... | 760 |
|R. B. Woodworth..... | 462 | Brown Type of Laboratory Agitator...T. S. Lawlor.... | 197 |
| Archbold, T. R.....Photography in Mining.... | 431 | Brunton, David W...Modern Practice of Ore-Sampling.... | 593 |
| Are We Progressing?.....S. A. Worcester.... | 856 | Ditto.....Modern Progress in Mining and | |
| Argo Smelter, Closing of the.....Editorial.... | 337 | Metallurgy in the Western United States..... | 453 |
| Arizona Copper Company..... | 778 | Bullion Mining Co., Ltd.....Company Report.... | 738 |
| Copper Deposits of Silverbell...C. F. Tolman, Jr.... | 710 | Tax Law in Nevada.....Editorial.... | 677 |
| Copper Fields, The Southern..C. F. Tolman, Jr.... | 356, 390 | Bunker Hill & Sullivan.....Company Report.... | 673 |
| Disseminated Chalcocite Deposits at Ray..... | | Burchard, Ernest F.....Fluospas in Colorado.... | 258 |
|C. F. Tolman, Jr.... | 622 | Burma, Petroleum in.....E. A. Wakefield.... | 500 |
| Arkansas Diamond Fields.....Austin Q. Millar.... | 534 | Ruby Mines of the Mogok Valley..... | 231 |
| Arnold, Ralph, and H. R. Johnson.....Sodium Sulphate | | Burrows, R. H.....Geology of Northern Mexico.... | 290, 324 |
| in San Luis Obispo County, California.... | 855 | | |
| Art of Placer Piping.....Dennis H. Stovall.... | 661 | C | |
| Asbestine.....E. Schaaf-Regelman.... | 289 | Calrnes, D. D...Yukon Territory West of Lewes River.... | 29 |
| Ashley, Harrison Everett.....Slime.... | 289 | Calculation of Blast-Furnace Charges...L. S. Austin.... | 723 |
| Asphalt Production..... | 472 | Ditto.....Percy E. Barbour.... | 664 |
| Assay Balance, New Inverted Type..... | 475 | Of Slag.....G. I. Dinwiddle.... | 420 |
| Of Cyanide Precipitate.....Frank A. Bird.... | 504 | | |
| Assays and Analyses, Accuracy in James W. Howson.... | 329 | | |

DECISIONS RELATING TO MINING..... 36

EDITORIAL.

ILL goes on the free list, according to action in the Senate. The Finance Committee was voted down. It is evidently a serious matter when the insurgent movement takes Root.

MARK TWAIN was a newspaper reporter in Virginia City when times were flush along the Comstock. It was there he learned to write. The Comstock lode has yielded over three hundred and fifty million dollars in silver—and one Mark Twain. Who shall balance the scales and say which has contributed the more to the joy of the world?

GOLD continues to flow in a steady stream from the Far North. The steamer *St. Croix*, from Nome, brought \$500,000 to Seattle on June 24. The *Dolphin*, from Sitka, landed \$840,000 the same day, and the following night the *Senator*, from Nome, brought in \$250,000. Probably none the less you will need your pocketbook when you visit the 'Pay Streak' at the Exposition.

POPULAR usage had already extinguished the awkward appellation of the Cananea, Rio Yaqui & Pacific railroad on the west coast of Mexico. The child was called by its father's name, and formal acceptance is now given by the incorporation of this company, with its allied concessions, under the title of Southern Pacific Railway of Mexico. Papers were filed in New Jersey, the authorized capital being \$75,000,000, in shares of \$100 each. The length of road now controlled by this corporation is 1600 miles, extending from Nogales by way of Guaymas, Culiacán, and Tepic, to Guadalajara.

ALUMNI of the Massachusetts Institute of Technology have subscribed \$150,000 toward the cost of a new site, which it is estimated would allow for growth during a period of 50 years. The phenomenal development of this splendid institution is shown by the fact that out of 4000 graduates 75 per cent have gone forth within the last 13 years. An appeal is made for funds to erect suitable buildings in accordance with plans which call for a total outlay of \$5,000,000. The services of the Institute in the advance of technology in this country have been so great that this appeal should meet with response from every corner of the United States.

DAN DE QUILLE was the pen name of Wm. Wright, who spent sixteen varied years in Nevada at the time when many things happened in the course of a single year. In his book, 'The Great Bonanza', from which we abstract an account of the finding of the Comstock, he has presented an intimate picture of the State and its people. We have Mark Twain's word that it is accurate, and, as that

gentle philosopher has said, one gets easily a surface knowledge of any remote country through writings of travelers, but the inner life is not often presented to the reader. The outside of a strange house is interesting, but the people, the life, and the furniture inside are far more so. This week we have tried to take our readers inside the miners' cabins of fifty years ago, and these two 'newspaper reporters' of bygone years have been our guides.

NOVA SCOTIA has not received its due share of attention from the Canadian Geological Survey, according to the *Maritime Mining Record*. It puts in a vigorous plea for further work by either Dominion or Provincial officials, pointing out that the only geological reports which treat of the Province in general, are nearly a half century old. Detailed reports and special studies are of high value and must be made, but our contemporary is right in insisting that general summary reports and hand-books must be available for ready reference if the ordinary man is to be helped.

PRIOR to the enactment of the Federal Mining Law of 1866 the local regulations on the Comstock limited each locator of a claim to a length of 200 feet, and gave to the discoverer a bonus of 400 feet. From this developed the custom of association claims, in which the several locators were tenants in common. These rights were often further subdivided, so that ownership of an undivided interest in the whole claim corresponding to one foot or less in length resulted. When companies subsequently were organized, stock was issued in proportion to the footage held by each interest. At one time it was the custom to quote in feet and inches, instead of shares.

A GREAT DEAL of moisture is shipped to the smelters, that might be eliminated, and thus effect important economies. For example, many moderately argillaceous ores contain 7 per cent or more of moisture. This material when dried will not re-absorb water from the air as readily as will coal or coke. In a good dryer from seven to eight pounds of water will be driven off per pound of coal burned. If ores were dried to one per cent moisture, the elimination of 6 per cent would consume only about 17 pounds of coal per ton, and at a Western price of \$10 per ton for bituminous the cost would be less than 9 cents, plus extra labor. On the Tonopah ore and concentrate, for instance, which contain approximately 7 per cent water, the freight rate, on a valuation of \$300 per ton, is \$18; a saving of 6 per cent in that case would amount to \$1.08 per ton. The Coeur d'Alene concentrate averages about 13 per cent moisture as delivered to the smelter. The freight on this material to Colorado is \$8, and a saving of 12 per cent would reduce the cost 96 cents per ton. The so-called 'sulphurets' from the mills on the California 'Gold Belt' contain from 3 to 10 per cent moisture, and the freight to market varies, according to distance, from \$1.50 to \$6. Even here it may pay to dry the ore. In many plants enough heat is going to waste to effect this saving. The Nevada silicious ores would not benefit by such treatment. They rarely hold more than 2 per cent of moisture,

and even when the amount is higher the loss inevitable from repeated handling of high-grade gold ore must be considered; it may easily offset the saving in freight.

A CONCERTED movement has taken place at Coalinga, California, to claim, as open to location, lands to which the Southern Pacific Company holds title. The case is one which is only of interest on account of the oil reserves which are involved. In its legal aspects no new or startling decision can be expected. Ascertainment of the facts will be the chief matter. A title to lands on the public domain becomes irrevocable after the lapse of six years. The statute of limitations enacted by Congress applies that rule to all patents issuing subsequent to 1891; the limitation was fixed at five years for patents granted prior to that date. The annulment of a patent is a difficult and complicated proceeding, even when there may appear to be good warrant for it. Reasonable evidence of wilful or technical fraud must be presented to cause the Secretary of the Interior to order a hearing by the Land Commissioner. After the evidence has been taken and sifted it is subject to the joint decision of the Secretary and the Commissioner whether sufficient cause for action exist, and if an affirmative conclusion be reached the evidence and recommendation for an action by the United States is passed to the Attorney General, who also possesses certain discretionary power. The courts are always loath to set aside a patent. This is an additional safeguard to property that has arisen from universal custom, so that the locators of claims on patented lands have at best a slender chance to make good their pretensions. It must be shown that the land was wrongly classified as agricultural land, and that either fraud or error was committed. If sufficient knowledge was available when the patents issued to have shown that the lands in question were probably oil-bearing, the Department of the Interior has power to so declare, and to recommend suit to annul the titles if such action be brought within six years from the date of issue.

Nevada City Mining Exchange.

It would be matter for regret if a mining exchange were to be opened at Nevada City. The bonanzas recently discovered at Alleghany within the 'sphere of influence' of that historic mining camp, have drawn the eyes of the world again toward the district. To employ the bunco-steering mechanism of a mining exchange, as mining exchanges are usually operated, would undo the good that should accrue to the 'gold belt' through the attraction of these glittering discoveries. A few years ago Nevada City issued a sane, sensible, business-like appeal to capital through its Chamber of Commerce, insisting upon the opportunities for permanent gold mining on a large scale in Nevada county. That was legitimate advertising, and the propaganda had better be left in the hands of such a representative body of men who can be trusted not to bring reproach upon the district. The hope of the California gold-belt, both in the northern and southern portions, rests not upon extracting occasional bunches of phenomenally rich ore, but upon

large operations founded on well developed veins. The ill fame of the California quartz mines among Eastern investors is due in large part to the erection of small plants on rich but narrowly limited ore-shoots. When the streak of fat had been consumed the mass of lean could not be economically treated. The Californian deposits in the foothill region suffer under the mis-nomer of 'pocket mines'. A distinction must be drawn between the true 'pocket' of ore and the rich ore-shoot through a low-grade vein. The failures made have emphasized the need of extensive development before installing reduction works. The spirit of those whose first thought, when something good turns up, is to establish a mining exchange, does not favor conservative operation. Such men are not thinking of making mines and of creating a solid industry, but of hypnotizing the gullible public into trading in stocks. We would be glad to see an exchange that was not diverted to wrong purposes, but we are certain that the outlook for a genuine revival of mining in Nevada and Sierra counties would be seriously clouded if the projected stock-laundry should be established.

Comstock Semi-Centennial.

There is a Nemesis who deals out retribution to bluffers. By men endowed with intellectual courage no form of dishonesty is held in greater contempt. The arch bluffer who fastened his name upon the great Comstock bonanza finds no one to lament his fitting end in a suicide's grave. This marvelous silver vein, which in its influence upon history has been second only to Potosí, was actually brought to light by two unpretentious Irishmen, Peter O'Riley and Patrick McLaughlin, hard-working men, modest and easily bluffed. The episode is striking, and in some aspects picturesque. The prospectors washing the gulch for gold, following their 'pay' up the side of a canyon, suddenly came upon a black substance which yielded a pale whitish gold in fabulous amount. Then appeared that lean lank Canadian, Henry Comstock, swinging lazily on his Indian pony, pausing for an idle word, and beholding proofs of a great discovery in the bottom of the rocker. With cool impudence the renegade demanded recognition of his ownership of the land, a claim fabricated solely out of his greed, and the Irishmen, disarmed by the very audacity of the stroke, submitted. It is a story which often has been told. Less widely known is the fact that Comstock, after dropping out of sight for a time with the petty winnings which he had made—for the bluffer's genius is not gifted in following an initial advantage gained—came back, and after a brief career of popularity, posing as a mining oracle, wasted enough of his admirers' money to open their eyes to his true character.

The Comstock was a well known mining camp for years before silver was discovered in 1859. As early as 1851 there were 200 rockers at work, and the output of gold for that year reached \$60,000. The place then bore the name of Gold Canyon. The first knowledge of these silver veins is said to have been obtained by Allen and Hosea Grosh, young men of superior talents, possessed of better understand-

ing than luck. Testimony of their discovery exists in correspondence of unquestionable authenticity. Both men came to tragic ends before the fruits of their prospecting could be gathered. Their methods were characteristic of the fertility of the pioneer in expedients; to reduce the silver sulphides to metallic form they had recourse to burning the pulverized mineral in dampened gunpowder. This method of assaying, if not scientific, was at least clever. Exact information regarding their discoveries died with them, a woman who had aided them with funds being unable to indicate the position of the treasure more closely than by pointing to the side of a mountain. The romance of this greatest of all American mining camps will form material for oratory at Virginia City on July 4, when 'all Nevada', so it is claimed, will work off its enthusiasm over the fiftieth anniversary of a discovery that has added nearly \$400,000,000 to the wealth of the world.

Uncovering of the greatest bonanzas in the Lode did not come until more than twelve years after the first discovery; then followed an orgy of speculation, a frenzy that stirred the West and sent thrills across the Continent year after year for the period of a generation. This was succeeded by an epoch of shameless systematic manipulation of stocks under control of a ring that lived by clever trading on a credulous public, 'washing' stocks, earning a little money now at one mine, now at another, so as to maintain delusion, profiting through graft on the installations for pumping and milling, and on the contracts for treating the ores, while bleeding those outside the ring by 'Irish dividends'. This infamy is practically ended. A new era has dawned, when legitimate work by honest and capable men is being done.

The Comstock has presented many problems of mining, milling, and finance, and many famous names are associated with it. Clarence King, G. F. Becker, John Church, Ferdinand von Richthofen, and other great geologists have studied the lode and made their contribution. Of these perhaps von Richthofen saw farthest; at least his predictions as to the position of the orebodies have been singularly verified. It was on the Comstock that square-setting as a method of holding ground was first employed on a large scale. It was here that the Washoe process of pan-amalgamation was developed from the slow patio method. It was in the Sutro that many problems in tunnel-driving were worked out, and it was on the Comstock that pumping large quantities of hot water from great depths was first accomplished. In the end the water won, and the miners were temporarily driven out, but now the solution of the problems of drainage seems to have been found, and deep mining will be a feature of the new development.

Elsewhere in this issue we print articles by men who tell of the Comstock from intimate knowledge, Mr. Joseph T. Goodman from the standpoint of a pioneer as the editor of the *Territorial Enterprise* in Virginia City for many years, beginning in 1861; Mr. Leon M. Hall, a distinguished engineer, born on the Comstock, to which he has devoted his life; and Mr. Whitman Symmes, another of the brilliant young engineers, entrusted with responsibility for the work of redeeming the name and fame of the historic camp.

BY THE WAY.

Mark Twain, in his famous book entitled 'Roughing It', first published in 1872, tells of 'flush times' in Silverland. Virginia, he says, came to be the 'livest' town, for its age and population, that America had ever produced. The sidewalks swarmed with people—to such an extent, indeed, that it was generally no easy matter to stem the human tide. The streets themselves were just as crowded with quartz wagons, freight teams, and other vehicles. The procession was endless. So great was the pack that buggies frequently had to wait half an hour for an opportunity to cross the principal street. Joy sat on every countenance, and there was a glad, almost fierce, intensity in every eye, that told of the money-getting schemes that were seething in every brain and the high hope that held sway in every heart. Money was as plenty as dust; every individual considered himself wealthy, and a melancholy countenance was nowhere to be seen. There were military companies, fire companies, brass bands,

SELLING A MINE.

Reproduced from 'Roughing It'.

banks, hotels, theatres, 'hurdy-gurdy houses', wide-open gambling palaces, political pow-wows, civic processions, street fights, murders, inquests, riots, a whiskey mill every fifteen steps, a Board of Aldermen, a Mayor, a City Surveyor, a City Engineer, a Chief of the Fire Department, with First, Second, and Third Assistants, a Chief of Police, City Marshal and a large police force, two Boards of Mining Brokers, a dozen breweries, and half a dozen jails and station-houses in full operation, and some talk of building a church. The 'flush times' were in magnificent flower! Large fire-proof brick buildings were going up in the principal streets, and the wooden suburbs were spreading out in all directions. Town lots soared up to prices that were amazing.

The great 'Comstock Lode' stretched its opulent length straight through the town from north to south, and every mine on it was in diligent process of development. One of these mines alone employed six hundred and seventy-five men, and in the matter

of elections the adage was, "as the 'Gould and Curry' goes, so goes the city." Laboring men's wages were four and six dollars a day, and they worked in three 'shifts' or gangs, and the blasting and picking and shoveling went on without ceasing, night and day.

The 'city' of Virginia roosted royally midway up the steep side of Mount Davidson, 7200 ft. above the level of the sea, and in the clear Nevada atmosphere was visible from a distance of fifty miles! It claimed a population of fifteen to eighteen thousand, and all day long half of this little army swarmed the streets like bees and the other half swarmed among the drifts and tunnels of the 'Comstock', hundreds of feet down in the earth directly under those same streets. Often we felt our chairs jar, and heard the faint boom of a blast down in the bowels of the earth under the office.

The mountain side was so steep that the entire town had a slant to it like a roof. Each street was a terrace, and from each to the next street below the descent was forty or fifty feet. The fronts of the houses were level with the street they faced, but their rear first floors were propped on lofty stilts; a man could stand at a rear first-floor window of a C street house and look down the chimneys of the row of houses below him facing D street. It was a laborious climb, in that thin atmosphere, to ascend from D to A street, and you were panting and out of breath when you got there; but you could turn and go down again like a house a-fire—so to speak. The atmosphere was so rarified, on account of the great altitude, that one's blood lay near the surface always, and the scratch of a pin was a disaster worth worrying about, for the chances were that a grievous erysipelas would ensue. But to offset this, the thin atmosphere seemed to carry healing to gunshot wounds, and therefore, to simply shoot your adversary through both lungs was a thing not likely to afford you any permanent satisfaction, for he would be nearly certain to be around looking for you within the month, and not with an opera-glass, either.

From Virginia's airy situation one could look over a vast, far-reaching panorama of mountain ranges and deserts; and whether the day was bright or overcast, whether the sun was rising or setting, or flaming in the zenith, or whether night and the moon held sway, the spectacle was always impressive and beautiful. Over your head Mount Davidson lifted its gray dome, and before and below you a rugged canyon clove the battlemented hills, making a sombre gateway through which a soft-tinted desert was glimpsed, with the silver thread of a river winding through it, bordered with trees which many miles of distance diminished to a delicate fringe; and still farther away the snowy mountains rose up and stretched their long barrier to the filmy horizon—far enough beyond a lake that burned in the desert like a fallen sun, though that, itself, lay fifty miles removed. Look from your window where you would, there was fascination in the picture. At rare intervals—but very rare—there were clouds in our skies, and then the setting sun would gild and flush and glorify this mighty expanse of scenery with a bewildering pomp of color that held the eye like a spell and moved the spirit like music.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. NOYES is at Denver.

J. E. SPURR is at Kofa, Arizona.

LESTER W. STRAUSS is at Lima, Peru.

FRED. W. BRADLEY is in the Coeur d'Alene.

RALPH ARNOLD has been in San Francisco.

R. S. BOTSFORD has left England for Brazil.

J. L. MAKEEVER was in San Francisco recently.

HOWARD D. SMITH has returned to San Francisco.

T. H. LEGGETT has returned to New York from Mexico.

R. CHESTER TURNER has returned to Berkeley from Mexico.

C. W. HAYES is visiting the oilfields of southern California.

A. A. STEEL is studying the Bingham Canyon mines, in Utah.

H. W. TURNER has returned to San Francisco from Prince Rupert.

LEONARD SIVYER has been examining mines near Clifton, Arizona.

FRED E. WRIGHT was married at Montreal, Canada, on June 16.

FRANK J. BOOTH has gone to San Juan Nepumceno, near Chihuahua.

E. S. PETTIS has left Costa Rica, Central America, for Mill Valley, California.

GEORGE CLARK GESTER has opened an office at 425 Washington street, San Francisco.

J. F. KEMP and a party of students have been working near Pottsville, Pennsylvania.

A. H. BROOKS sailed from Seattle for Cordova, Alaska, on the steamer *Northwestern*, July 1.

THEODORE GROSS, who represents the London Venture Corporation and the Hirsch Syndicate in New York, has gone to London.

ROBERT ANDERSON is completing the geological survey of the oilfields in the Carriso plain of San Luis Obispo county, begun by Ralph Arnold.

General Mining News.

ALASKA.

The Manley holdings in the Hot Springs district have been leased to Tom Aitken.—A test lot of 1000 tons of ore from the Delos Fraber vein above Cleary was run through the mill at Fairbanks. The ore was taken out at a depth of 20 ft. and milled about \$40 per ton.—The first shipment of gold in the registered mail from the Tanana district amounted to over \$1,000,000.

ARIZONA.

COCHISE COUNTY.

B. Q. Musgrove and associates have a lease and bond on the Paradise holdings of F. G. Bernondy and W. P. Wright.—W. L. Masters shipped 90 sacks of silver ore from the Treasure Hill mine to the smelter at El Paso.—T. E. O'Brien has taken a lease on the Bunker Hill mine near Cerbat.—The property of the North Bisbee Development Co. in Dixie canyon has been transferred to the Bisbee Coalition Co.—Cross-cuts from the 1500-ft. level of the Junction shaft of the Superior & Pittsburg have opened good ore-bodies.—The Copper Queen is carrying on a number of experiments, using steel and concrete reinforced by ½-in. iron bars as a substitute for mine timbers.

GILA COUNTY.

The Arizona Commercial Co. is confining the development work to the 700-ft. level of the Eureka shaft.—The Old Dominion Copper Co. has contracted to supply the Miami company with 1,000,000 gal. of water per day.—Plans are under way for the construction of a mill for the Miami Copper Co. having an initial capacity of 2000 tons, which will be afterward raised to 3000 tons per day.—The adit to intersect the vertical shaft of the Live Oak Copper Co. is in about 1000 ft. and has cut 150 ft. of concentrating ore.—On a car of ore shipped from the Copper & Silver Zone mine the return was 93 oz. silver and 2% copper. H. W. Clark is in charge of the work.

PINAL COUNTY.

The Ray Consolidated Copper Co. has let a contract for 4000 tons of structural steel to the Kansas City Structural Steel Co. The steel is to be delivered in Kelvin this fall to be used in the erection of the 5000-ton concentrator and smelter. The Ray company has also let a large contract for heavy timber and lumber to be used in the construction of the big mill.

YAVAPAI COUNTY.

Work is to be resumed on the Alvarado mines at Fools' gulch. A Butters filter will be installed.—The 200-ft. shaft of the Champion group on Lynx creek is being unwatered. John Edwards is superintendent.—The Goldsworthy placer ground on Lower Lynx creek has been taken over by Wilbur Treadwell.

CALIFORNIA.

FRESNO COUNTY.

A surveying party under the direction of C. P. Bowie has begun staking the route of the new Associated pipeline from Coalinga to Port Costa. It will run direct to Tracy, thence to the bay parallel with the Bakersfield line.—W. W. Sweet, who held an option on the property of the West Coalinga Oil Co., has bought the property for \$42,000. It comprises 57¼ acres.

INYO COUNTY.

(Special Correspondence).—The Skidoo mine is producing at the rate of \$24,000 per month. During May 824 tons were treated. The bullion extraction was \$20,473 and cyanide extraction \$1000. Development and operation costs amounted to \$6,404.91, leaving a net profit of \$15,417.46.—The Conklin Mining Co. has installed a 10-stamp mill and 7000-ft. tramway at its Monster property. A wagon-road has also been built from the mine to Brown station on the California & Nevada railway. Large reserves of ore have been opened and prospects are good for a steady production.

—The King lease has opened a vein of free-milling ore on the estate of the Inyo Mines Syndicate at Benton.—Mount & Denison are sinking on a 5-ft. vein of \$7 ore.—The Shive-Untank lease at Chedago has developed a 3-ft. vein of excellent ore at a depth of 125 ft.—The Lucky Jim is sacking ore for shipment to the Keeler smelter.—In the Bishop district most of the old properties are working steadily. Lack of ample finances is holding back rapid developments in some cases, but this feature is manifesting encouraging improvement.

Bishop, June 26.

A cloudburst in the mountains surrounding Bishop has caused the destruction of the diverting dams of the Nevada-California Power Co., causing the shut-down of many mines throughout Nevada. The company has three plants at Bishop operated by water-power. Two of these were completely closed and the third badly damaged.

MONO COUNTY.

(Special Correspondence).—Surveyors are mapping out a route for a railway from Gardnerville to Bodie, which will pass directly through the Masonic district. This will enable the various companies to ship their higher grades of ore to the smelters and devote their attention to milling their immense deposits of low-grade quartz. The Pittsburg Liberty, the largest property in the camp, is producing \$25,000 per month. Ten stamps and a cyanide plant are in commission.—At the Golden Cycle the shaft is down 110 ft., with a 4-ft. vein of ore assaying over \$40 per ton at the 83-ft. level. The north drift has cut a 7-ft. vein said to run more than \$25 per ton.—Lessees on the Snowdrift have opened a strong body of ore assaying \$25 per ton.—At the Casa Diablo, drifts are being driven from the 100-ft. level to cut several veins opened higher up. The mill is running steadily and two bars of bullion are shipped each month.

Masonic, June 28.

NEVADA COUNTY.

The shaft at the Union Hill mine below Grass Valley will be sunk from the 600 to the 650-ft. level and a cross-cut run to the vein. A Cornish plunger pump with a capacity of 1200 gal. per minute has been ordered by the company.—In the 150-ft. drift from the 900-ft. level of the Oustomah a shoot of ore has been cut that assays from \$250 to \$500 per ton. E. H. Wilson is manager.

PLACER COUNTY.

Charles Peach has purchased the C. A. Reed quartz mill near Lozano's in the Ophir mining district.

SACRAMENTO COUNTY.

Clinton L. White, Mayor of Sacramento, has called a meeting of representative citizens of the cities of that district to consider means of regulating the work of dredges.

SAN BERNARDINO COUNTY.

(Special Correspondence).—A 16-in. streak of bonanza ore has been cut at a depth of 185 ft. in the Ram's Horn at Silver Lake. Samples of the ore assay \$3000 per ton. The adit is in 180 ft. in milling ore.—Ore assaying from \$5 to \$90 per ton has been struck in the shaft at the Avawatz, and at the 65-ft. level a 3-ft. body of fair-grade ore is being opened. C. S. Eichholtz is superintendent.—The adit at the Old Glory is in 180 ft. and some milling ore has been opened. F. M. Myrick is superintendent.—The shaft at the Eaton group at Seventeen Mile Point is being sunk from the 200 to the 300-ft. level and is opening bodies of milling ore. John L. Witney is manager.—The Todhunter-Felix lease at Hart has cut the southern end of the rich shoot exposed in the shaft. It is 18 in. wide and assays about \$50 per ton.—The Crackerjack Bonanza is driving a cross-cut from the 200-ft. level of the main shaft and is in 70 ft. Three thousand tons of ore assaying \$5 to \$80 per ton are stored on the dump. F. L. Flourman is manager.—Providence, Rhode Island, people have purchased the Oro Belle Extension, Oro Extension, Oro No. 1 Extension, Ruth, Ruth Extension, Red Boy, Red Boy Fraction, and Estrella claims and have started vigorous work. Three shafts are going down at the Ruth, Red Boy, and Oro Extension.—C. A. Leager and S. T. Grant, of Goldfield, have acquired 10 claims

at Shadow mountain and are pushing work. The vein is 3 ft. wide and carries gold and copper.—The Alta mine is shipping ore to Selby.

San Bernardino, June 25.

SHASTA COUNTY.

The Uncle Sam mine above Kennett has been purchased from Fred H. Dakin by I. O. Jillson and A. L. McIntosh.—The iron smelter at Heroult has closed down temporarily for repairs. These will take about three months and the smelter will commence commercial operations this fall.

SIERRA COUNTY.

The American Mining & Development Co., operating a drift gravel mine at Snowdon Hill, seven miles above Camp-tonville, has just completed the work of installing a three-drill Sullivan air-compressor and an electric lighting plant. One machine-drill is now running in the bedrock adit, and one at the 250-ft. station where a cross-cut is being driven across the channel. The plant is operated by water-power. Pay-gravel has recently been found and the construction of a sluice for washing the gravel is under way. Roy G. Mead is manager.—Henry C. McPike, a San Francisco attorney, has been appointed receiver for the famous Sixteen-to-One and Bonanza King mines in Alleghany, in the suit brought in San Francisco by M. Vander Beugle. The latter demands an accounting of all moneys and ore received by E. H. Wilson since their partnership.—The adit of the Twenty-One mine at Alleghany cut the vein and opened an orebody carrying a high percentage of arsenical sulphide. F. M. Phelps and associates are operating the mine.

SISKIYOU COUNTY.

The Welsh mine on Grouse creek is running three giants and one hydraulic elevator.—The mill of J. M. Morrison in Quartz valley has been started.—The Phillips brothers cleaned up 100 oz. of gold from the last run of the Saint George placer near Hawkinsville.—It is reported that the Blue Ledge Copper Co. is to build a railroad and smelter.—The Zarina Mining Co., which is operating the Taylor Lake mine on Taylor creek, is moving its mill and expects to have 10 stamps in operation within another month.—The Boundary mine on south fork of Scott river has begun operations, and has a crew of men laying the pipe-line and cleaning out the ditches and repairing flumes.

COLORADO.

BRECKENRIDGE COUNTY.

The Puzzle and Ouray properties are being re-opened and the mill put in working order. W. T. Hayes is in charge of the work.

CLEAR CREEK COUNTY.

(Special Correspondence).—R. B. Morton, operating the Commodore property on Red Elephant mountain, has commenced shipping smelting ore. Stoping is in progress upon a body of mineral that is from 18 in. to 2 ft. wide, and from returns the ore has been found to contain on an average of 190 oz. in silver per ton.—Noonan & Oxley have taken a lease upon the upper dump of the Lamartine mine. There is estimated to be 50,000 tons of this stuff, all of which is to be hauled to the Jackson mill at Idaho Springs for concentration. During the early history of operations no ore was marketed that carried less than \$60 per ton, and as a result the dump will probably average more than \$20 per ton.—J. G. Roberts, who constructed a 100-ton rough-jigging plant at the lower dumps of the Lamartine, is operating the plant with two 12-hour shifts. The product, after treatment, is hauled to the Jackson mill at Idaho Springs for the separation of the lead, zinc, and iron.—The water from the Seven-Thirty shaft on Sherman mountain was struck last Saturday, and the old workings are now gradually draining themselves. For some time 10-ft. holes had been kept ahead of the shooting to avoid any danger. Owing to the great pressure from above no one will be allowed to enter the Burleigh workings, as it is feared by the manager, J. H. Robeson, that the ground may give way suddenly, allowing a deluge of water to make its escape. As near as known there are between 7 and 10 miles of underground workings, all of which are filled with

water from the third level down to the seventh.—John L. Malm, inventor of the Malm process of chemical-electro ore extraction, and G. J. Bancroft examined the East Griffith mine on Griffith mountain, and it is reported that at an early date work will be put under way upon a 50-ton plant for the treatment of the ore found in the various workings of that property. The East Griffith has large reserves of lead-zinc ore, which assays high in gold and silver, and it is claimed by Mr. Malm that this ore is adaptable to his method of treatment. D. W. Hoover, of Denver, is manager. Georgetown, June 23.

OURAY COUNTY.

John Keleher shipped two cars of ore from his lease on the Neodesha mine.

GUNNISON COUNTY.

The 426-ft. raise from the adit level of the Blistered Horn mine near Tincup is completed. A. Lejune, the manager, expects to have the mill running some time this summer.—The Gold Links mine is preparing to install a hydro-electro plant. Richard Kilvert is superintendent.—Teams are hauling ore from the Morning Star mine to Sargent. John C. Reagan is in charge of the work.

SAN MIGUEL COUNTY.

The property of the Ophir Consolidated Mining Co. of Ophir was sold to the Milwaukee Trust Co. for \$335,988 at a trustees' sale. The property was closed by the bondholders.

SAN JUAN COUNTY.

The Highland Mary mine is shipping ore regularly to the Durango smelter. George Hill is superintendent.—The concentrate from the trial run of the Arpad assayed 5 oz. gold, 28 oz. silver, and 68% lead. William Harrison is in charge of the work.

SUMMIT COUNTY.

The Hoosier Gulch Co. will work the Bemrose placer at the head of the Blue river this summer. J. F. Lincoln is manager.—The Relling dredge at the Mekka placer east of Breckenridge took out \$13,000 in one week.

TELLER COUNTY.

The connection has been made between the south heading of the International shaft of the Roosevelt tunnel with the Portal heading. The alignment and grade are exact. Measurements taken from the records of the engineer show the total distance covered in the two headings to be 7975 ft. In addition, the north heading from the Intermediate shaft has been carried 1875 ft., a total distance for all three headings of 9850 ft. Work was started on the tunnel May 11, 1907.—A Franklin electric 10-drill compressor has been purchased by the Doctor Jack Pot Mining Co. and will be installed at the Davenport shaft. A. E. Carlton is president.—The Gold Issue Mining Co. is installing an aerial tram by which ore is to be transported from the Midget mine on Gold hill to the Gold Issue mill on the northwestern slope of Carbonate hill, about two miles distant.—The Elkton Mining & Milling Co. has declared the regular bi-monthly dividend of 1¼c. per share.—The shoot on the No. 3 south vein of the Victor Consolidated Gold Mining Co. has been cut on the 1300-ft. level. Average samples assayed about \$165 per ton.

IDAHO.

IDAHO COUNTY.

The Jennings Dredging Co., of New York City, has closed a contract with the Hammond Manufacturing Co., of Portland, Oregon, for the construction of a gold-mining dredge to be installed on its property on Little Elk creek, the specifications calling for a dredge having a capacity of 2000 cu. yd. per day and be ready for delivery by September 15.—A 4-ft. vein of rich ore was cut on the Center Star group owned by James Murphy, Herman Brown, and Charles Tiedeman.

OWYHEE COUNTY.

A consignment of electric machinery has been received by the Silver City Mining & Milling Co. J. F. Cook is manager.

SHOSHONE COUNTY.

A decision has been rendered in favor of the Tamarack & Chesapeake, against the Snow Peak M. Co.—The adit of the Great Northern M. Co. east of Burke is in 400 ft., the last 30 being in chlorides that assay 14 oz. silver per ton. Ed. Eisman is manager.—The mill on the Granite-Allie property near Murray is being overhauled. The company will commence shipping its high-grade lead-silver ore at an early date.—Report of the Copper King Mining & Smelting Co. of Mullan, issued to the stockholders, shows that 1007 ft. of adit has been run since December 15, at an average cost of \$9.54 per foot, making a total of 1107 ft. The directors have authorized an assessment of 1c. per share on the capital stock.—The Federal Mining & Smelting Co. paid a dividend of 1¼% on the preferred stock recently. The disbursement amounts to \$210,000.—The Gold Back mine near Murray has been bonded by the Duluth Development Co. and a double-compartment shaft started.—Ore assaying \$2200 per ton has been cut on the property of A. B. Rhude.—The Alice Mining Co. has bought the Milwaukee Mining Co.'s 100-ton mill on the Formosa property near Gem, and will ship it to the Alice mine.—The 700-ft. adit of the Coeur d'Alene Central cut a vein that assays 26 oz. silver and 1% lead.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—Wilcox & Co. have just finished three holes in the grayish flint deposit north of Galena, finding ore from 165 to 220 ft., the cuttings running from 15 to 18% zinc.—The Old Happy Hollow tract south-east of Galena has been bought by Decker & Co., of Joplin.—The Clermont company has bought the Kathleen mill in the Zincite camp and will re-erect it.

Galena, June 28.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Integrity Mining Co. on the Carter land north of Webb City is re-building the mill which was burned last year. The new plant will be a 250-ton structure.—The new mill on the Ave Maria lease in the new sheet-ore field south of Webb City has been put into commission and the first turn-in has been made.—The Grace Ping Co. has put up a new concentrating plant of 150 tons at Duenweg.—The Cock Robin Co., in the Chitwood camp, has put up a new 200-ton mill which has been running successfully about three weeks.—The Red Dog mine in North Webb City has installed a 200-hp. electric plant.—The Barfet Mining Co., operating in Turkey Creek valley north of Joplin, has struck a rich lead deposit.—A good drill-strike has recently been made on the Shiffer-decker land west of Joplin by J. E. Stillwell.

Joplin, June 29.

MONTANA.

MISSOULA COUNTY.

The Success Mining Co., which holds an option on the controlling interest of the Monitor mine, has commenced to unwater that property under the supervision of J. Leslie Bailor.

SILVER BOW COUNTY.

A consignment of dredging machinery has been purchased by M. H. De Hora, manager for the British Butte Mining Co., from the Risdon Iron Works of San Francisco.

NEVADA.

ELKO COUNTY.

John R. Pattison has completed his mill and commenced to work the dump of the old Navajo mine at Tuscarora. The Navajo was never opened below the 600-ft. level, but is credited with a production of \$7,000,000.—E. A. P. Johnson, P. C. Johnson, R. T. Noble, and W. D. Bray have purchased the Young lease on the placer properties of the Nevada Hydraulic Mining & Milling Co. and have equipped them with a complete hydraulic plant.

ESMERALDA COUNTY.

The Hubbard lease in the Luckyboy district is shipping 75 to 80 tons of ore per day.—The shaft of the Spencer

lease is down 300 ft. and shipping will commence this month.—A hoist is being installed on the McAfee lease.—A shoot of high-grade ore was cut on the McCormick lease while cutting the station at the 100-ft. level. Thomas G. Murphy is in charge of the work.—The Red Top Mining & Leasing Co. is carrying on development work from the 575-ft. level.—The Golden Daisy at Diamondfield cut an 8-in. vein that assayed \$120 per ton in gold and silver. H. A. Morrison is operating the property.—There are 12 tons of ore that will assay between \$200 and \$250 per ton ready for shipment at the St. Ives lease. A. A. Codd is manager.—The shaft of the Railroad lease on the Conservative property is down 145 ft.—J. A. Burton is to start work on the Montezuma Gold King property north of Montezuma.

HUMBOLDT COUNTY.

The raise from the 425-ft. level of the Wihuja lease in the Seven Troughs district is in good ore. As soon as this shoot is opened the ore will run through the Coalition mill.

LINCOLN COUNTY.

The Oregon-Pioche Mining Co. is to resume operations on its mine in the Highland district.—C. Hunsaker has sold his interest, 37,500 shares, in the Occidental Mining Co. of Eldorado to C. G. Austin and Buffalo associates. E. P. Jeanes will be superintendent.—The drift on the vein of the Lenape mine cut an excellent shoot of copper ore. The shaft is to be sunk to the 300-ft. level and lateral work carried forward from that point.

NYE COUNTY.

(Special Correspondence).—The placers are continuing to show up well, and in many cases are exceeding earlier expectations. In the main gulch, west of the camp, approximately 160 shafts have been sunk and the gold zone demonstrated for six miles. The channel in some places is 700 ft. wide, but will probably average about 300 ft. The gravel-beds range from 3 to 5 ft. thick at bedrock, the depth varying from 40 ft. near the camp to 100 at the edge of Smoky valley. Operators state that the value is about \$12 per yard of washed gravel, while the cost of handling and treating is \$2 to \$4 per cubic yard. With the coming of the electric-power supply from the Nevada-California Power Co. it is expected that this cost will be materially reduced. Several placer claims have changed hands recently, and the excitement manifests no sign of abating.—The Murdock Placer Co. has secured the Bright August lease on the main gulch for \$4000 and will install an electric hoist and other machinery in order to carry on extensive work. Loftus & Davis are interested. The company is also operating several other claims.—A 2-ft. body of \$60 ore has been opened at a depth of 325 ft. in the Plamenaz Union No. 9, and is showing increasing strength with development. About 4 in. runs into high-grade shipping ore.—The Irvine lease on Broncho has cut a shoot of ore said to average \$45 per ton at a depth of 15 ft. The shaft is going down steadily.—A 3-ft. vein of ore running \$20 to \$30 per ton has been cut at a depth of 125 ft. in the Morning Star.—At the Toyahe a 4-ft. body of \$20 quartz has been struck. Two leases are being worked in addition to the parent company. The ore occurs in porphyry.—At the Manhattan Consolidated developments are going forward with machine-drills. It is said that fair-grade ore is being found. The property is equipped with a 50-hp. hoist and air-compressor.—A suction dredge will shortly be installed on the September claim in the main placer gulch.

Manhattan, June 28.

The first lease to start work in the Ellendale district is owned by N. B. Phillips on Jim Clifford's ground.—The Keane Wonder at Bullfrog shipped 8 bars of bullion worth \$22,000.—The last shipment of Tramp ore from the Clothier-Gingles lease to the smelter at Needles was settled for on the basis of \$95 per ton.—The regular dividend of 25c. per share and an extra dividend of 10c. per share has been declared for July 21 by the Tonopah Mining company.—Work on the north cross-cut on the 765-ft. level of the Montana-Tonopah is to be rushed, as this is prospecting new ground. The west drift on the 390-ft. level is following the Triangle vein, which averages from 2 to 3 ft. of milling

ore.—The West End Consolidated is shipping about 85 tons of ore per week to the smelter. Fred Corkill is superintendent.—A new 10-drill compressor, motor, and transformer has been installed at the MacNamara mine.—The Belmont has commenced sinking from the 1100 to the 1200-ft. level.—At the Montgomery-Shoshone ore is being stoped on the third and fifth level. A new Chilean mill is to be installed shortly, the concrete base of which is already completed.—The Crystal Bullfrog custom mill has commenced operations and the cyanide plant will be ready to start about the 15th of this month. The mill is equipped with three single stamps. The first ore run was that of the Bowen lease on the Denver claim. It averaged about \$50 per ton.—Lateral work has been started from the 123-ft. level of the Indiana.

OREGON.

GRANT COUNTY.

The Independence mine in the Granite district is being unwatered. Walter G. Gleeson is manager.

JOSEPHINE COUNTY.

A water-power plant is being installed at the Oriole mine. J. C. Mattison is manager.—A new mill is being erected at the Sugar Pine mine.

UTAH.

BEAVER COUNTY.

The shaft of the Cupric Mines Co. cut shipping ore at a depth of 300 ft.—The Cave mine is shipping one car of copper ore per day.—A body of copper ore was cut by the shaft of the Majestic mine at a depth of 360 ft.—The Horn Silver Mining Co. sent a carload of ore to Salt Lake to ascertain if it could be worked by the Behrend system of dry concentration. M. C. Morris is manager.

JUAB COUNTY.

The Lehl Tintic mine shipped 25 tons of lead-silver ore to the Tintic smelter that assayed 56% lead and 25 oz. silver per ton. Theodore Nichols is superintendent.—A cross-cut has been started from the 300-ft. level of the Provo property.—Higgenson & Baxter shipped a car of ore from their lease on the La Clède mine.—A new hoisting plant has been placed at the Gruttl shaft.—The first shipment of ore from the Chief Consolidated Mining Co. was sent to the Tintic smelter June 25. Walter Fitch is manager.—The Montana mine is sinking a three-compartment shaft.—The old Gold Blossom mine is being re-opened.

SUMMIT COUNTY.

Work will be resumed on the Nelson Queen mine east of Park City as soon as electric power can be brought to the mine.—A new orebody has been opened in the old Carbonate Hill mine and shipping will be resumed.

TOOELE COUNTY.

The first shipment of ore for the current season from the property at Ophir of the Lion Hill Consolidated Co. was settled for on June 23 by local smelting companies. The shipment consisted of one car, which was divided into two lots. Lot No. 1 assayed: gold 0.26 oz., silver 581.6 oz., and lead, 15.5%. Lot No. 2 assayed: gold 0.309 oz., silver 235.2 oz., and lead 9.7%. George St. Clair is manager.

WASHINGTON.

STEVENS COUNTY.

Conrad Wolfe, manager of the United Copper Co., near Chewelah, has begun work on a spur six miles from Chewelah to a point near the portal of the tunnel, now being driven to tap the vein.

CANADA.

ONTARIO.

The Empire mine is to sink to the 200 and cross-cut at the 155-ft. level.—The Silver Cross mine at Cross lake has been sold to Pittsburg capitalists. W. H. Jeffery is now manager.—The Temiskaming & Hudson Bay Co. has declared a dividend of \$5 per share on the old capitalization.—The shaft of the Gifford Extension in the Coleman district is down 86 ft. A pipe has been laid to the Ophir plant and sinking on the 30-in. calcite vein will be continued to the 200-ft. level.

BRITISH COLUMBIA.

(Special Correspondence).—The Highland mine, a silver-lead property, in the Ainsworth mining district, was bonded by American mining men last week. Despite the fact that the arbitration committee appointed by the Dominion, mine operators and miners had come to a satisfactory agreement; the men have voted down the recommendation of the board and an unsettled condition still prevails in the coalfields. It is generally understood, however, that a real majority of the men are anxious to return to work and that pressure will be brought to bear that will end the strike shortly. Several of the different districts have made application to the Minister of Labor for investigation boards to inquire into the strikes in their particular localities, so that they can get things settled and resume work.—A company, known as the Head Syndicate, has been formed for the purpose of developing the Head-Martin coal-lands that adjoin the property of the International Coal & Coke Co. Leslie Hill is consulting engineer and manager.—The Bounty mine with 16, Silver King 49, and Yankee Girl with 51 tons, are on the shipping list for this district.—The Dewdrop Fraction, Sunbeam Fraction, and Hattie mineral claims have been purchased from the Provincial Government by the Rossland syndicate of miners, who will put a force to work on development immediately. This property is in the south belt portion of the camp and adjoins the Richmond and Hattie Brown, being on the silver-lead reef that runs through this part of the camp.—P. F. Roosa has been relieved of the receivership of the Dominion Copper Co., and the New Dominion Copper Co. taking over the interests and property of the old company, Mr. Roosa has been appointed manager, which position he held in the old company before he was appointed receiver. It is thought that the new company will have things in form to resume work at the mines about August 1.—At the Donald Copper property the company is building ore-bins and a road to the railway, which is a mile distant. Continued development on this property is proving some good ore.—A force of men has been put to work getting things in shape at the Sunset mine for the resumption of work. It is said on good authority that work will be going on at the Providence mine at Greenwood before long. The company shipped 700 tons of high-grade gold-silver ore in 1907, and 50 tons last year, as little work was done. The management has been trying to place a bond issue to raise funds for work.

Rossland, June 25.

G. Weaver Loper, chief owner of the Lucky Jim mine near Kaslo, announces that a contract has been made with the Great Northern Railway Co. to use the steamer *Kaslo* to carry ore to Troup Junction for shipment to the United States at the rate of 200 tons per day. Eighteen hundred tons of ore have been shipped that assayed 53% zinc.—W. J. Wilson and P. Burns have sold the Highland mine near Ainsworth to J. S. Airheart and associates of New York. Work has been started and it is anticipated that a first shipment will be made this month.—A rich copper strike was made on the Kimberly property, 2½ miles from Kamloops, owned by H. Beckman.

MEXICO.

MEXICO.

The Seguranza Mining Co. is hurrying work on the line to bring electric power from Sultepec to its new 100-ton custom cyanide plant at Zacualpan. Joseph Nibel is manager.

SONORA.

A concession for the construction of four railroads in the northern part of the State has been granted to the Cananea Consolidated Copper Co. by the Government.—Development work at the Santa Rosalia south of Cananea is exposing good orebodies, but in the Sonora River country the protracted drought has stopped prospecting and closed some of the mines.

TAMPICO.

A gusher flowing 200,000 bbl. of oil per day has been struck on the property of George I. Ham near Tuxpan.

Special Correspondence.

GOLDFIELD, NEVADA.

Consolidated for May.—Dam Washed Out.—Florence.—Daisy.

An official report of the results of operations by the Consolidated Mines Co. in May, which has been delayed owing to the absence of the officials in New York, shows that the company produced and treated 21,630 tons of ore. The gross recovery was \$762,748, and the net recovery \$662,000. The total cost, including mining, milling, transportation, and general expense, was \$6.117 per ton. Ore shipments amounted to only 156 tons, which yielded a net return of \$92,797, and the net profits for the month were reduced to \$606,759 through the payment of a considerable sum in bullion taxes and certain other expenses. Last week's output from the mills was curtailed, for the reason that both

On the Florence, connection has been made between the bottom of the main shaft and the raise from the cross-cut at 500-ft. depth from the Engineers shaft. By July 15 it is said the new machinery for the mill will be in place. The plant will be driven by belt instead of by gear, as heretofore, eliminating a large degree of liability to breakage. The Florence mill is still treating ore averaging about \$11 per ton, and chiefly taken from lease dumps. Officials of the Florence company have paid to the assessor of Esmeralda county the sum of \$10,018, representing bullion taxes, which they at first refused to pay, together with penalties for delinquency and fees payable to the district attorney for collection.

The recent discovery of rich ore in a lease on the Daisy is proving better than was indicated by first reports. The ore is exposed in a raise above the 360-ft. level, and the vein has been opened for 30 ft. in length, showing 2 ft. of ore, a portion of which assays \$350 per ton gold. Development in the Daisy progresses as heretofore, and shipments will shortly be increased. The 400 and 500-ft. workings are in good veins, but have not yet found the ore-shoots exposed above.

Interest centres at Virginia City this week, and many are preparing to attend the three days' celebration there of the semi-centennial of the discovery of the Comstock lode.

LONDON.

Tax on Mineral Lands.—Old Mining Laws.—Derbyshire Lead.—Kalgoorlie Mines.—Great Boulder Perseverance.

The owners of mineral lands in Great Britain are aghast at the proposals of the Government for levying a tax on unmined minerals. The proposed tax is aimed at the land-owners who become immensely wealthy through their mineral rights and who draw large incomes from royalties without any risk. Nobody could honestly object to a tax on such royalties if it were possible to provide that the land-lord would not pass it on to the mining companies or the public. The present proposition provides for a tax of one-half penny per £1 per annum on the "present profitable value" of the mineral values of the estate. The "present value" of ore deposits is an intricate actuarial problem. It is not easy to explain in a few words what is meant by present value, but as an example may be cited the case of something which is worth a hundred pounds but cannot be sold for a hundred years. It is obvious that such a thing is not worth a hundred pounds now. Thus it will be seen that a landowner who possesses coal deposits that will last for a hundred years at the present rate of working will not be called to pay a tax on the total ultimate obtainable profit. There are a vast number of considerations involved in the calculation of the present value of a mineral estate. In the absence of willing buyers and sellers such valuations can never be actually made and under the proposed law they will be purely arbitrary. Perhaps, however, the proposition will not be adopted by Parliament after all.

It is probably not generally known to American readers that the mining laws of Great Britain are not uniform, and that within so small a boundary there are many sets of widely different laws. For instance, the county of Derbyshire has its own laws relating to metalliferous mining. Perhaps it would be best to call them customs rather than laws, for they have been handed down from almost prehistoric days. Here the right of the finder to lead ore is similar to the old German common mining right. The finder has absolute right to work his discovery without having to bargain with the owner of the surface land. The amount of compensation to be paid to the latter is determined by an official called the bar-master, together with a jury. If the finder stops working for a fortnight his mine may be jumped without notice. Derbyshire is underlaid chiefly with Carboniferous limestone and Millstone grit, with some eruptive rocks here and there. In days gone by it has yielded galena freely, and a number of mines are still being worked profitably. Fluorspar occurs plentifully, and during recent years substantial amounts have been mined and taken from the dumps to meet the

Map Showing Position of Virginia City and Goldfield.

were closed for over 24 hours, and operated at only part capacity for another day, owing to the washing out of a diverting dam at the plant of the Nevada-California Power Co. on Bishop creek, in California. The Mohawk mine is now supplying the principal tonnage for these mills, the larger part being taken from the big stopes in the south-eastern portion of the claim, between the 450 and 600-ft. levels. Development is progressing from the lower levels of the Clermont shaft, levels having been started at 730, 860, and 1000 ft., and from the station at 600-ft. depth, where the connection was made with the main Mohawk shaft. A drift has been started to the north, toward the Laguna claim, and with a view to cutting the extension of the ore-body from which a large tonnage is being stoped on the Lucky Boy claim. This orebody is yielding a regular production averaging \$50 per ton, and despite the presence of faults the ore remains continuous for over 200 ft. and shows a face of uniform character varying from 15 to 30 ft. wide. Levels have been driven from the Mohawk shaft under the workings of the old bonanza leases, where large quantities of high-grade ore remain, and much valuable ore has been recovered from the caved ground.

demands of iron-masters in England and America. My special reason for referring to this matter now is that there has been a heated dispute at Matlock over the possession of a mine in the neighborhood called the Providence. Matlock is one of the beauty spots of England and is a centre for visitors who believe in hydropathy. There are a certain number of producing mines in the neighborhood, but the Providence has not been very active as a producer for 50 years or more. In fact it was supposed to be worked out. The local authorities had decided to buy a strip of sylvan country for the purpose of making a park, when they were suddenly confronted by a gentleman who claimed to be the owner of the Providence mine, which happened to be situated on the property. He declared that he was the owner and that he was producing ore regularly; consequently he asked for a sum of money in exchange for his rights. The chairman of the local council argued that this gentleman had not worked it for some time and put in a claim to be allowed to work it himself. In that way it was hoped that the local council would be able to gain possession and by working the mine in a nominal manner, just sufficient to comply with the law, would be freed from further disputes. A court was therefore held by the bar-master and jury to decide the dispute, and feelings ran high, ending practically in a free fight. Eventually the court found that work had not been continuous and handed the rights over to the chairman of the council. His duty to the public in his capacity as private citizen will be to work the property in the most unostentatious manner possible. I believe, however, as a matter of fact, that there is little ore left, and probably it will only need one miner to pick out such ore as is to be found, and take as long to do it as possible.

One of the noteworthy points in connection with the Great Boulder Proprietary gold mine at Kalgoorlie is that its output has shown a gentle but steady advance from the commencement in 1895 to the present day, and in this way presents a distinct contrast to others in the district, which made big profits at first and afterward fell on evil days. The output at present is about £49,000 per month. During the year 1908, the output of gold was valued at £578,704 and the net revenue was £331,855, out of which £262,500 was distributed as dividend. The ore treated amounted to 165,428 long tons, and the working costs were 25s. 8d. per ton, which is equivalent to 22s. 9d. per short ton. This is a rise of a shilling per ton over the previous year, due to increased costs of fuel and material, extra repairs to plant, and higher wages. The treatment plant is being enlarged and before long the yearly tonnage should be increased to 200,000 tons. The ore deposits show no sign of exhaustion and the reserves are given at 731,426 tons averaging over 16 dwt. per ton. The way the deep levels are opening up is most gratifying. At the lowest level, that is, the 2200 ft., a body of ore 5 ft. wide and averaging over 2 oz. per ton for 166 ft. has been found.

The most recent information relating to another of the Kalgoorlie mines, the Great Boulder Perseverance, gives some indication that this mine is about to open up into practically a new mine at depth. In the early days large profits were made from the rich ores at upper levels, and afterward came a sensational collapse. Subsequently, under the efficient direction of the consulting engineers, Hooper & Speak, the position was retrieved, and profits have been made from comparatively low-grade ores. For example, during 1908 a net profit was made of £46,725 by the treatment of 204,406 tons of ore which produced 71,025 fine ounces. There is still some 390,000 tons of 6½ dwt. ore and 200,000 tons of ore which is put down as probably payable, all of which is above the 1100-ft. level. During the last few months the development below this level, recommended by Mr. Speak last year, has proved remarkably successful, especially at the 1750 and 1900-ft. levels, and ore running as high as 2 oz. per ton has been found. It is too early as yet to give any definite estimate of these deposits, but the directors have cause to feel pleased at future prospects. A few months ago the management of the mine was taken over by Hooper & Speak, and the operations are under the superintendence of Ernest Williams.

NEW YORK.

Cost of Copper. — British Columbia Copper Co. — Tonopah Belmont. — Curb Market. —

It has lately been reported in the technical journals that many of the Western copper mines are producing copper at or below 7c. per pound. This has led copper consumers to expect a reduction in copper prices. With the view of showing the cost of copper production, the Amalgamated Copper Co. has published the costs at its Butte mines. From the figures given, it appears that these range from 13c. per pound at the Parrot mine, and 11c. at the Anaconda, to 10½c. at the Butte & Boston. The mines in Utah and Nevada, in which the company is interested, however, are doing much better. Though not referred to in the published statement, it is well known that they are producing copper at from 6 to 8c. per pound. Negotiations are in progress between the representatives of the Boston Consolidated Copper Co. and Utah Copper Co. with a view to uniting the two companies. Should this be accomplished, the negotiations between the representatives of the International Smelting Co. and the directors of the Colorado Mining Co. in regard to the sale of that company's Iron Blossom mines and Knight smelter, at Tintic, Utah, which have lately fallen through, will be resumed.

The British Columbia Copper Co. some months ago closed its mines owing to the reduced price of copper. While they remained closed the price of the company's shares declined. Advantage was taken of this by others to purchase a controlling interest. At the recent meeting of the company in New York, as a result Adolph Lewisohn was elected to the position of managing director. The control of the Dominion Copper Co. has passed in a similar manner. Mr. Lewisohn is associated with the new International Smelting Co., and it is probable that the two larger Canadian copper companies will be guided in their future operations by the International rather than by the Amalgamated company. The British Columbia Copper Co.'s mines and collieries will be re-opened immediately. Instructions have been issued to the mine officials to blow in three furnaces and maintain an output of 2000 tons per day. Recent improvements in the furnaces are expected to result in a lowering of the cost of copper production below 7c. per pound. The company has 1,400,000 lb. of copper on hand which cost 8c. per pound to produce, and is being held for better selling prices. The production during the next few months will be stored.

Work is being actively carried on at the Guanajuato Consolidated mine, Mexico. The manager reports that the mill crushed 7383 tons of ore in May with a return in bullion of \$62,250. Concentrate sales brought additional returns.

Considerable interest was manifested on the New York Curb when the telegram was posted announcing the deep-level strike in the Tonopah Belmont. It appears that a body of auriferous silver ore between 4 and 5 ft. wide has been struck in a winze from the 1100-ft. level. This is the deepest orebody yet cut at Tonopah, and curb brokers will watch its development with much interest. Since work was abandoned in the low levels in the Tonopah Extension, Midway, and Tonopah mines, interest in Tonopah mining investments has almost ceased in New York. Investors conceived that the Tonopah mines contained only superficial deposits and exchanged their holdings in Tonopah mines for shares in mines on other fields. Local curb brokers state that they recognize the fact that Tonopah mines are among the steadiest producers in the West, and if it can be established that the deposits continue at depth, a demand of large proportions for Tonopah mining shares will result. Mining transactions have been of only limited extent on the New York Curb during the past few weeks. The public is not at present speculating on either the Stock or Curb exchanges. Whatever transactions are recorded daily, are mostly on professional account. Although everyone expects to witness a new mining boom as soon as the country recovers from the depression, few at the present time take any interest in mining enterprises. There are no new promotions being undertaken, and established mining enterprises find much difficulty in securing financial advances.

JUNEAU, ALASKA.

Perseverance Gold Mine.—Milling Methods.—Sheep Creek Power Plant.—Prince Rupert.

The Perseverance Gold Mining Co. resumed operations in Silver Bow basin about June 1, John R. Mitchell being general manager. This basin is four miles easterly from Juneau, and is at the head of Gold creek, which drains into Gastineau Channel. The ore-bearing zone consists of veins, lenses, and stringers of quartz in a body of slate and has a greenstone foot-wall, but the hanging wall is not definite. The width of material which is profitably mined is from 60 to 80 ft. Along a strike of nearly 2000 ft. the width is determined by sampling and assaying, rather than by any visible boundary on the hanging side. The ore carries free gold, which occurs in the seams and cleavages of the quartz and slate, and also in association with iron pyrite, galena, and a little blende. All the ore broken is milled, including many lenticular thin bodies of barren slate, as well as stringers of barren quartz. The entire unsorted mass is said to average \$3 per ton in gold, with a variable amount of silver. The orebody is opened by a cross-cut, which intersects it 2200 ft. from the portal, and 1200 ft. below the surface, measured on the dip of the lode. From the place where the cross-cut enters the orebody a drift has been driven 1300 ft. east on the ore and 560 ft. west. There are nine air-drills in use, including the Wood, Waugh, and Murphy. At present haulage is by mule-power. A surface tramway delivers the ore from the

Alaska-Perseverance Mine and Mill.

cross-cut to the mill, where there are crushers—one No. 5 and two No. 3 Gates. The crushed ore, ranging in size up to 2½ in. diam., is conveyed to the mill-bins, from which it feeds into the twenty 5-stamp batteries. It is stated that 70% of the saving is made on the amalgamating plates. The pulp passes from the plates to James concentrating tables, of which there are 34. The concentrate amounts to 400 tons per month, consisting of iron, galena, and zinc, carrying 2 oz. gold per ton, with some silver.

On the Sheep creek side of the mountain the Perseverance company has commenced two cross-cut adits from a point 180 ft. above tide-water, to be driven to the same orebody on which they are now mining, but which will cut it at a depth of 2400 ft., measured on the dip. This plan contemplates the driving of two parallel adits, 30 ft. apart and 11,000 ft. long. Mr. Mitchell claims that better ventilation and cheaper first costs are possible with two single track adits and electric haulage, than with one of sufficient size for a double track. A gas producer plant is being installed near tide-water, on the Sheep creek side; one Weber engine has been installed already and three others will be put in later. The gas engines will be used to operate electric generators. The plan is eventually to erect a mill of large capacity on this side, where snow will not interfere.

At Prince Rupert satisfactory progress is being made in the building of the Grand Trunk Pacific. The grade is nearly complete for 100 miles up Skeena river and rails will be laid this fall. Beyond this point the route is not announced, but the discovery of a satisfactory coalfield in Bulkley valley may have some bearing. At Prince Rupert building docks is going forward rapidly.

KALGOORLIE, WESTERN AUSTRALIA.

April Output.—Golden Ridge Reserves.—Graphite in Ore.

The April gold output from the whole State amounted to \$2,920,000 and dividends \$1,250,000. Following are the returns from the principal mines:

| Name. | Tonnage. | Value. | Profit. | Dividend. |
|---------------------------|----------|-----------|----------|-----------|
| Associated | 11,680 | \$113,000 | \$41,000 | |
| Asso. Northern Blocks.. | 3,613 | 33,000 | 13,000 | |
| Golden Horseshoe | 24,773 | 260,000 | 100,000 | \$450,000 |
| Golden Link | 3,116 | 25,500 | *1,500 | |
| Golden Ridge | 2,265 | 24,000 | 14,000 | |
| Gt. Boulder Proprietary. | 16,262 | 247,000 | 130,000 | |
| Gt. Boulder Perseverance. | 18,825 | 140,000 | 28,000 | |
| Great Fingall | 14,053 | 74,000 | *8,500 | 46,000 |

*Loss.

As the Lake View Consols interest has been acquired by another syndicate, crushing operations have ceased at the former mill; and most likely a small mill will be erected on the Eclipse lease of the Golden Link. When working the oxidized ore some few years ago, the Link company had a 20-head battery and cyanide plant at work, the stamps crushing 9½ tons each per diem for a considerable period. This mill was struck by lightning and totally destroyed, everything being motor driven.

The ore reserves in the Golden Ridge are announced as 55,000 tons, with a reasonable value of \$11.50 per ton. This mine is locally owned, is 14 miles southeast of the Golden Mile, and is opening up rather well. Cross-cutting is in progress at 500 ft. In the other levels the lode is up to 5 ft. in with, and assays \$14 per ton. A 20-head battery and cyanide plant is in operation, and treatment is plain salting.

In the Boulder No. 1 lease, the Ivanhoe east lode is 10 ft. into the property with payable ore. The east branch of the No. 3 lode in the Horseshoe was cut at 2000 ft., gold and tellurides showing, the lode being 5 ft. wide, worth \$30 per ton. Good reports come to hand from the Sons of Gwalia, and a good deal of ground has been pegged in the hope of getting the lode.

Along the east side of the Golden Mile, and even in the Great Boulder, there is a fair amount of graphite, mostly in the form of a slate and schist. In some parts of the mines it occurs in bands, and in others finely distributed. When it occurs in bands it can be picked out, but when distributed it so far cannot be dealt with satisfactorily. In the dry-crushing mills it will pass through the roasters almost unchanged, and when the roasted ore is mixed with the circulating waters the trouble commences. In such ore it may be noticed floating upon the pulp in the grinding pans. Here it collects on the overflow lip, and no doubt a great deal floats away with the pulp to the settlers, and also with the thick slime to the agitators. The circulating waters are generally weak KCN washes—say, 0.04—from the filter presses, and contain from 50c. per ton upward in gold. No doubt some precipitation of the gold takes place in the settlers, but it is evidently when in the agitators with a strong solution—0.08 KCN—while the gold is being dissolved, that most of the damage by the graphite is done. Extraction fails of course, but this residue can be re-treated successfully. By increasing the final heat in the furnaces a great deal of the graphite may be destroyed, but such heat would probably sinter the ore, which is not wanted. It will be interesting to follow the work in connection with the treatment of the Lancefield ore, which is supposed to have graphite distributed throughout the lode. Many well known metallurgists and others have tried but failed.

LIMA, PERU.

Copper Production.—*Santa Inez.*—*Chimbote Coal and Harbor Syndicate.*—*Huaylas Valley Railroad.*

Mining conditions in Peru are slowly improving after the set-back following the drop in the price of metals. The copper production for the past year (17,000 tons at 2240 lb.) shows a decided increase, due to the steady monthly gain of the Cerro de Pasco smelter production; this increase was offset by the shutting down of many small shipping mines which had yielded a good output in the time of better prices. The Cerro de Pasco company is gradually reaching its maximum production, due to the successful operation of the reverberatory furnaces for the fine ore, four of which, now treating 100 tons each of calcine daily, have been running for some months. The fifth furnace is suffering from lack of coal, which is only a temporary condition. The 400 tons of calcine, produced from eight McDougall roasters, require 160 tons of coal. The screening plants, at the mines, are not yet in operation; as a result the percentage of coarse ore for the blast-furnaces is not over-abundant; however, the present curtailed supply shows a 10% increase in the capacity of the four water-jackets, which will undoubtedly be improved as soon as the screening plants are running. Lack of cars on the railroad from Morococha has seriously interfered with the handling of the ore from that district—about 150 tons daily. The production of copper for the month of May will exceed 3,000,000 lb., and by the beginning of July, barring the unforeseen, the monthly production should be about 4,000,000 lb. It is expected that by the end of the year the company will be producing at the rate of 50,000,000 lb. per year.

The decline in the price of silver has not seriously affected the silver producing mines, that is, those mines which chiefly yield silver. The Santa Inez mines have apparently again found the shoot of ore which some years ago produced a yearly net profit of £40,000 over a period of seven years; but difficulty in handling water has handicapped development. At present there seems to be considerable interest taken in gold mining, particularly in vein mines. The latter industry, with two or three exceptions, seems to have been overlooked in the quest for copper and silver.

The Chimbote Coal & Harbour Syndicate, Ltd., reports satisfactory progress of its undertaking. The syndicate was formed in October last, and owns extensive coal claims situated about 64 miles from the coast and has been granted by the Peruvian Government a concession to build a railway from Tablones to Recuay, about 130 miles. From Tablones to Chimbote harbor, some 30 miles, a line is running, owned by the Peruvian Corporation, Ltd., and the concession gives the syndicate power to parallel this line if required. The syndicate also has a controlling interest in the Pier company at Chimbote harbor, the company having an exclusive landing monopoly for 16 years. This is one of the finest natural harbors on the South American coast. Concessions for the construction of the railway had been previously granted, but owing to insufficient financial resources to complete the work the concessions were abandoned. From Tablones toward the coalfields about 28 miles of embankment work has been carried out, and has been surveyed and passed by the Government, so that only some six miles of such work, plus rail laying and bridges from Tablones to the syndicate's coalfields, remains for the completion of railway communication with the harbor. The Peruvian Corporation, Ltd., has promised friendly support to the undertaking and to assist in establishing railway communication between the syndicate's coalfields and the port of Chimbote. As soon as through communication is established it will be possible to deliver at least 150,000 tons of coal per annum at the seaboard. There is a large demand for coal, 1,500,000 tons per annum being shipped from Great Britain, Australia, and other points to the West coast. The Chimbote coalfields have already been partly opened.

The coal is stated to outcrop for 20 miles along the route of the railway. From the coalfields on to Recuay, along the Huaylas valley, the railroad will pass through the most densely populated district in Peru, the inhabitants number-

ing some 500,000. A considerable amount of work has already been carried out beyond the coalfields, including seven rock tunnels.

SALT LAKE, UTAH.

East Tintic Activity.—*Water in Centennial-Eureka.*—*Fink Makes Blister Copper.*—*Silver King Suit.*—*Consolidation of Bingham Mines.*

Within the past six months the activity in the East Tintic district has been especially great. Within a radius of less than a mile are a dozen hoisting plants now actively engaged in bringing waste and ore to the surface. Most of these shafts have a shallow depth, the deepest being the East Tintic Development, which is 350 ft. from the surface. The Grutil, Eureka-Lilly, Tintic Standard, Montana, Big Hill, and several other groups are being developed, and some ore has been found in each of these properties. The East Tintic Development is extracting ore from a depth of 235 ft., and will soon have the drift from the third level in the ore. Near the surface this ore carries much lead, but in depth the silver increases perceptibly. More companies are preparing to engage in mining in that part of the district, and indications point toward this becoming one of the richest areas in that camp. Among those interested are the Knights, Snyders, Loose, Haldaways, Bestlemeyer, and others who are classed among the pioneers at Tintic.

Edward Fink has completed a test in his furnaces, in one of which he made a 90% copper matte, and in another blister copper. It is understood that Samuel Newhouse, who has been called to New York, will arrange for the construction of a permanent plant and install the Fink process. Some lead ores from Alta and other nearby camps are to be tested in these furnaces, and if successful Fink smelters will be manufactured and forwarded to isolated Western camps.

Permission to file an amended complaint has been denied the Conkling Mining Co., in its suit to recover damages from the Silver King Coalition Mines Co. In the original petition the Conkling company alleged that the Silver King had wrongfully extracted a million dollars worth of ore from that lode. One-fourth interest in the property is owned by the Silver King and three-fourths by the Conkling. A survey of the claim has shown that the Silver King extracted a bonanza orebody clearly within its end lines, and that the Conkling survey overlapped the Silver King between about 140 ft. It is understood that this decision practically settles the controversy, and that the Silver King Co. will be allowed to mine the ore in that portion of its territory without further interruption.

A heavy flow of water has been tapped in the drift off the 2200-ft. level of the Centennial-Eureka mine, owned by the United States Smelting Co. Large pumps have been ordered, and the management hopes to have the water under control so that driving can be continued within a couple of weeks. A heavy cave also occurred in the mine a few days ago. In some of the abandoned workings the timbers had slipped, and ground from the fourth to the eighth levels fell. It is claimed that no damage was done to the mine, all the ore having been extracted.

Officials of the large Bingham copper mines continue to deny the report that there will be a consolidation of properties. D. C. Jackling, of the Utah Copper, says that he can see no advantage in taking in other mines. It is known that Boston Consolidated officials have refused to consider any proposition by which their property should be put in with Utah Copper on the basis of two shares of Boston for one of Utah Copper. That there will be a time in the course of a few years when it will be of immense value to both companies to join hands in the operation of these properties is conceded by all interests, but it is believed that they are too far apart at this time to make a deal possible. E. A. Wall, who sold his entire holdings in Utah Copper, and has since taken a large block of the Boston Consolidated, is said to be one of those opposed to consolidation. It is believed here that the Utah Copper interests would be willing to pay a large sum for the control of the Boston Consolidated, and this may eventually be the manner in which the properties will be consolidated.

BUTTE, MONTANA.

Butte & Superior.—Original Con.—Sarsfield.—West Butte.—Highland.—Little Rocky Mountains.

In the Butte & Superior, driving is in progress from the 1400-ft. level west. On the 1200-ft. level the Jersey Blue vein has been cut, and on the 1400 a cross-cut is being driven to cut the Black Rock vein. This may be broken into any day. Three hundred feet east of the shaft on the 1200-ft. level the big zinc vein has been found, and numerous cross-cuts show it to be 55 ft. wide. The ore will assay about 25% in zinc. One carload per day is being shipped to the new zinc concentrator at the Butte reduction works.

The figures for the year's work, ending June 1, 1909, in the properties of the Original Consolidated Mining Co., given to the county assessor for taxation purposes, show the net proceeds to have amounted to \$152,625, which is \$7000 less than for the year ending June 1, 1908. This company is a close corporation, the stock of which is held by W. A. Clark. It owns the following mines: Original, West Steward, Fashion, Woolman, Burt, Dives, Little Treasure, Skip, Whitmore, Mount Moriah, Late Acquisition, and Late Acquisition Spur. The figures show: ore mined, tons, 248,761; gross yield per ton; \$8; cost of mining, \$1,068,683; freight on ore, \$56,683; cost of reducing, \$755,062; amount expended for labor, \$660,283; cost of mine supplies, \$408,400; net proceeds, \$152,625.

Operations on properties east of Butte are becoming more active each week. The Sarsfield, situated at the mouth of Park canyon, a half mile or so from the Pittsmon property of the East Butte company, has been taken over by lessees. The shaft, already 150 ft. deep, was cleaned out and a cross-cut was started to catch the north and south fault which runs through all the properties in that part of the belt. Another tunnel which runs into the fault is being cleaned out, and in this is shown 12 or 15 ft. of good shipping ore, a mixed silicate and oxide. In the bottom of the shaft there is a vein showing several feet of sulphide ore. The owners of the Sarsfield are Charles Mattison, Jerry Clifford, James A. Murray, Mrs. James A. Forbis, John Macginniss, and Charles S. Warren. Negotiations are under way to effect a combination of what are known as the Freudenstein with other interests in the southwestern portion of the city, and to re-open some of the old workings. A combination of this kind would result in the development of the Elba, North Pole, Germania, Humboldt, and other properties.

In the Highland district, 17 miles south of Butte, a great deal of work is being done this season, and several good strikes are reported. On the Richmond claim, operated by Bluff, of Butte, six or eight feet of gold ore have been uncovered which will assay \$25 to \$30 per ton. The Tiltens, operating what is known as the Old Nevins property, have sunk a shaft 300 ft. deep, and have many thousands of dollars' worth of ore blocked out. During the past two or three years this property has shipped about \$20,000 worth of ore. It was a good producer in the early days. The property in the Highland district is situated along an immense contact of granite and limestone that runs in a horseshoe course around the base of Red mountain. It is only recently that the prospectors and miners there have prospected this contact, which is now taken up for a distance of about seven or eight miles, and there are between 15 and 20 prospectors and miners at work.

Reports of the work being done on the August mine, near Landusky, in the Little Rockies, indicate that an unusually rich property is being opened. Last week a shipment of ore to the East Helena smelter of the A. S. & R. Co. assayed from \$350 to \$1000 per ton in gold. The company is employing 35 men, and has much ore blocked and much on the dump, but owing to the heavy roads at this time of the year, no effort is being made to ship regularly. The property is owned by Phillips & Whitcomb, Coburn brothers, and L. R. Goslin. The coming summer will see active work in the Little Rockies. There are more prospectors in the hills than usual, and development is being planned by many persons interested in that part of the country. It has long been recognized as one of the best districts in the country for ores amenable to cyanidation.

TORONTO, CANADA.

Cobalt Dividends.—La Rose.—Nipissing.—Elk Lake.—Gowganda.—Sale of Gillies Limit Lots.

A number of the leading Cobalt mines have declared dividends this month, including La Rose 3% with 1% bonus; Nipissing 3% with 2% extra; Temiskaming & Hudson Bay \$3 per share on the old capitalization, or 300%; Crown Reserve 6% with 9% bonus; Buffalo 5% with 3% bonus; and Right of Way 6%. Nevertheless the stock market continues dull and depressed. The market has been unsteady ever since the Temiskaming passed its dividend. Confidence does not seem to have been restored by the Directors' statement, justifying the act on the ground that a cash reserve and funds to install a concentrating plant were needed, the company having low-grade ore on the dumps ready for concentration of an estimated net value of \$500,000. The public naturally asks, why under the circumstances the company declared high dividends earlier in the year unless with the object of manipulating the stock? The La Rose annual statement presented at the shareholders' meeting at Montreal June 15, is a splendid showing. The total output for the twelve-month ending May 31 was 6164 tons containing 3,010,831 oz. silver, valued at \$1,364,372, and the net operating profit \$1,093,572. It cost about 16c. per ounce to recover this silver and develop the several properties, leaving a profit of about 35c. per ounce. Probably more than two-thirds of the total tonnage were taken from the La Rose main workings. The one fissure which has given the mine its distinctive character has altogether produced so far over 4,000,000 oz. silver. The Nipissing annual statement showed a surplus on June 14 of \$1,092,000, including cash in hand and ore at the smelter, in transit, and at the mine. The Nipissing led the shipments last week with 198 tons. A good vein has been cut at the Badger in driving in the 100-ft. level and followed for over 40 ft. A specimen carrying rich native silver and containing over 3000 oz. per ton has been placed on exhibition in Toronto. Both the Badger and the Beaver are preparing to make initial shipments and there is considerable rivalry as to which will take the lead. The Kerry Mining Co., operating a leasehold owned by the Peterson Lake, has found a narrow but rich vein containing native silver, stated to assay over 4000 oz. per ton. High-grade ore is being taken out of the Little Nipissing. The Beaver vein at the 200-ft. level was lost for a short time, but has been picked up and is about 10 in. wide with 4 in. of good ore. The installation of the new plant, which will be completed in a few days, will enable the company to have four drills at work in place of two. The Silver Cross mine in the Cross Lake section of the camp, has struck a lead 8 in. wide at the 65-ft. level of No. 2 shaft, composed of native silver, niccolite, and smaltite.

The shaft at Elk Lake Discovery mine is down 154 ft., being the greatest depth so far reached in the Elk Lake district. Driving has been commenced at this level toward vein No. 4, which shows native silver at the surface. Work has been begun on the Mother Lode in Elk Lake district. The shaft will be put down to 150 ft. The Otisse has cross-cut the first of nine veins to be tapped at the 75-ft. level. It is composed of a 6-in. calcite vein with a good showing of native silver, and some 2 ft. of fissure filling shot with silver leaf, and a calcite band shows rich with silver. At Gowganda the steam-plant of the Bartlett is in full operation and the shaft is going down at the rate of 12 ft. per week. The shaft at the Boyd-Gordon is down 87 ft., at which level a vein 4 in. wide, carrying about 3000 oz. silver per ton has been reached by cross-cutting. The Ontario Government has sold by tender, subject to working conditions and a 10% royalty, 15 lots comprising in all 870 acres of the Gillies Limit, adjoining the Cobalt area, the total price received being \$74,643. A large number of tenders for the other properties offered were rejected as being too low. The sale excited but little interest among mining men, owing to the withholding by the Government of all particulars tending to throw any light upon the value of the property. In fact nobody outside of official circles knows whether there is an ounce of silver on any of the properties.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Timber amounts to only about 15% of the cost of shaft-sinking, even in localities of extremely high prices.

Tantalum is derived from tantalite, FeTa_2O_6 , and columbite, $(\text{FeMn})\text{Nb}_2\text{O}_6$. It is used for making filaments for electric lights.

Copper ores are peculiarly subject to secondary enrichment, and usually show a marked increase in metal at the base of the oxidized and top of the sulphide zone.

Mount McKinley is the highest mountain on the North American continent. It rises to 20,300 ft. in height, about 10,000 ft. above the crest line of the Alaskan range to which it belongs. The mountain is a dome of granite.

Oxidized ore of the same grade can usually be treated more cheaply than sulphides. This is not, however, always true. Low-grade ores of lead, zinc, and copper, in the form of sulphides may be concentrated when oxidized ores having the same percentage of metal would be valueless.

Schists may be chemically and mineralogically identical with slates, but are made up of coarse particles, or possess a wavy structure, or both features. Both slates and schists may have originated in deposits of identical character, but have undergone different processes of metamorphism.

Theoretical horse-power required for pumping may be determined by multiplying the number of gallons per minute by the amount of head in feet and dividing by 4000. The result must be increased to allow for friction of pipe and inefficiency of plant, according to the character of the installation.

Earthquakes have been explained, and methods of observation and measurement given in great detail, in a paper recently printed by Harry F. Reid, of Baltimore, bearing the title 'Conditions Leading to Tectonic Earthquakes, Instruments Used in the Study of Earthquakes, Etc.' The paper was presented to the American Philosophical Society in Philadelphia.

Sampling of ore in the ground gives usually a higher average value than actual mill-runs. In three West Australian gold mines two years' sampling gave assays 12% above the mill-yield, plus the content of the residue. On the Rand the actual extractions are generally about 78 to 80% of the average shown by sampling in the mine, and 90 to 92% of the assay value of the mill-heads. At Broken Hill, New South Wales, three lead mines yield about 12% less than the sampling indicates to be present.

Location of an excessive area does not invalidate a mining claim, as a rule, unless the excess be so great as to raise presumption of bad faith. The ex-

cess is cast off, and the claim is valid for the balance of the area. When the senior locator has himself specified the extent of his claims in each direction from the discovery point, it would seem only reasonable that he could not take advantage of his error in making an excessive location. The courts would be disposed to grant this excessive area to a junior overlapping locator.

Fine gold in sands and gravels is often difficult to save, and sometimes success baffles the operator completely. It must be realized that the term 'fine gold' does not refer to any definite variety of gold; if it did, one system would fit all cases. The gold in different districts varies widely in character. The size and shape of the grains differs from point to point, in one place being round, in another oval, again flat and round, or flat and oval, smooth or rough as to surface, regular or irregular as to shape. All these conditions affect the rate of settling of the particles in the sluice-current. Still another factor is the specific gravity of the particles, due to the alloy-ratio, or fineness, of the gold, which is also a variable.

Saving fine gold in placer mining is accomplished in a great variety of ways. The riffle-system is still the most successful, but there are a great many different designs. The angle-iron type of Hungarian riffle is one of the most successful. This consists of a series of small angles, with the horizontal leaf about 1 in. wide, set so that it points down-stream. The object is to produce an eddy under the projecting leaf, to facilitate arresting the gold. It is found useful at times to alternate these riffle-frames which are set with the riffles transverse to the current, with other plain iron-bar riffle-frames set in the direction of flow through the sluice. Mercury is usually fed at intervals into the top of the sluice. The ordinary form of wooden riffle, 1 in. deep, made in frames for convenience in handling, will do good work, which is improved by screening the coarse material. Revolving amalgamators, of the barrel or cylinder type, occasionally improve the saving, but at increased cost.

Black sands in themselves have no market at present. They are a complicated mixture of magnetite, ilmenite, and a host of iron-bearing minerals and basic silicates. Some gold invariably goes over with these sands, and hence they are occasionally worth saving on that account, though rarely. The only efficient means is to concentrate the screened sand on Wilfley or other table concentrators. It is a mere question of what will pay. The resulting concentrate is seldom rich enough for shipment, and requires local treatment for extraction of the gold. Amalgamation is commonly unsuccessful, but cyanidation will give good results. It may be noted that after having passed gravel over one set of riffles, it often pays to screen a little closer and pass the undersize through a second sluice with another set of riffles. A second washing of gravel-tailing which had been hydraulicked has in some cases proved as profitable as the original treatment. A case recently occurred also in a well known dredging field where it has paid to re-dredge the tailing piles.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Vacuum-Pump in Cyaniding.

The Editor:

Sir—In reference to the letter, signed by Alfred James, published in your issue of May 15, I am sorry to disagree, especially in public, with an old friend and colleague, but I cannot let Mr. James' statement that "the vacuum-pump and the cyanide process were both introduced into South Africa before J. S. MacArthur ever arrived in that territory," pass without correction. The facts are that the Cassel Gold Extracting Co. controlled the MacArthur-Forrest patents, and sent expeditions to various parts of the world with a view to the installation of the process. Early in 1889 Alfred James went to South Africa, and in the autumn of the same year returned, reporting that there was a good field for the process. Arrangements were made, and late in the same year this company sent Mr. James, at the head of a few skilled men, to erect a cyanide plant for demonstrating the applicability and commercial value of the process in South Africa. The directors of the Cassel company at the same time decided to send me as their technical manager, to take the responsibility of the actual demonstration. I arrived in May 1890. The plant was not quite finished, and it was only in June, and under my supervision, that the first demonstration of the cyanide process in South Africa was made. No one wishes to minimize the part Mr. James took in the introduction of the process. He then displayed all his characteristic energy and skill, but, like other able men, he is able to make a mistake, and has done so on this occasion.

JOHN S. MACARTHUR.

Glasgow, June 4.

Santa Eulalia Camp.

The Editor:

Sir—Believing that the numerous errors of statement made by the compiler of the article on the Santa Eulalia mining camp in the issue of the MINING AND SCIENTIFIC PRESS of January 2, are apt to confuse, I beg leave to note some of them as follows: As to values: the assumption, "that the mining of those days was on rich ores from the very surface," in connection with the later statement as to the present "output not exceeding an average of 20 oz. for the better-class ores," is misleading. In the eighteenth century, measured in terms of gold, silver was worth about two and one-half times as much as at present, while labor costs and conditions in Chihuahua were such that one peso would produce as much silver as six pesos will now. In other words, while it is a fact that the early miners followed only 'pay' from the surface down, as a rule 10 oz. was as good to them then in Santa Eulalia as 60-oz. ore is now. As to the better class of ore today, averaging but 20 oz., it is ridiculous. The statement issued by the San Toy

Mining Co., January 15, concerning their Galdeana mine, says: "the ore blocked out may be estimated to contain over 30,000 tons running 20 oz. silver, not of sufficient value for profitable extraction at present prices of metal." But current published statements give orebodies in their Juarez mine of upward of one million tons of 60-oz. ore. Fifty dollars per ton is a frequent basis of settlement. It is well known that orebodies of vast extent in the Dolores contain from 2000 to 20,000 oz. That these things are kept quiet does not make them non-existent.

As to the formation, that the lower portion of the elastic covering is of "sedimentary" instead of "aqueous-explosive" origin can well be doubted. Faulting to the extent mentioned is inconsistent with Kimball's survey. Nor do the strata at the summit of the dome as given by Kimball dip first at 5 and lower down at 30 to 40°, but just the reverse. The statement that the breccia and conglomerate at Sierra Mojada are estimated at 1800 ft. is confusing, inasmuch as this base of conglomerate is always limited in depth, and that only the 'cantera' proper in its various forms has attained this thickness. Contact deposits above the lime exist. Deep workings so far confirm the northerly direction of the genetic fracture-zone referred to by Argall, and so far no deep mines have been found far away from it. That some connection exists between the present topography and the leaching of the silver downward along this zone will no doubt be recognized later, as well as the lateral extent of this district.

LOUIS LANE.

Chihuahua, Mexico, June 20.

Official Definitions of Mining Terms.

The Editor:

Sir—A pamphlet entitled 'Suggestions to Authors of Papers Submitted for Publication by the United States Geological Survey,' by G. M. Wood, has been recently issued, and is of much value to all who write on geology and mining. Of special interest to mining engineers is a section entitled 'Reports on Mining Districts'. It would obviously be helpful to have an established standard for the guidance of engineers in preparing mining reports, and a publication from the Geological Survey should carry great weight in establishing such a standard. A careful perusal, however, of the section above mentioned leads to the conclusion that it has not been subjected to critical revision. It is proposed, therefore, in the interest of a standard nomenclature, to review briefly some points which excite interest or criticism.

Ore.—"A natural association of minerals from which one or more of the useful metals may be extracted." This definition precludes the application of the term ore to a single mineral. Under this rule, a magnetite or hematite, unmixed with other minerals, would not be an ore of iron. This is obviously contrary to established usage and not to be commended. The definition of an ore having already been freely discussed in these columns, further comment is unnecessary.

Gangue.—"The term 'gangue' is properly applied only to the earthy or non-metallic minerals that are

of common occurrence in ore deposits, such as quartz, barite, chlorite, fluorite, calcite, and dolomite." This definition could not be applied in the case of a copper or silver ore disseminated through a sandstone or other rock, for the rock is not a mineral; yet, in this case, it must be called gangue, for there is no other term in common use to designate valueless material enclosing or associated with ore.

Vein.—"An ore-bearing vein is a single body of metalliferous minerals occupying or following a fissure, both walls of which generally, but not invariably, are well defined." The expression "body of metalliferous minerals" seems to be inapplicable to a quartz vein carrying auriferous pyrite. Pyrite is a metalliferous mineral, but it is inadvisable to use the term metalliferous with reference to quartz, because it does not always carry metals.

Lode.—"Where several veins are so closely spaced that the ground between them becomes in places ore-bearing, and in the whole width constitutes an orebody, the assemblage is called a lode." This definition of lode is clear and supplies a concise description of a type of ore deposit which deserves differentiation. It remains to be seen, however, whether this definition will be generally accepted. In common usage the term lode is synonymous with vein, and has been so accepted in several important court decisions.

Shear Zone.—This is defined geologically as "the zone along which the rocks have been sheeted or laminated by a shearing stress with some lateral movement, but which is by no means necessarily or even commonly mineralized." The suggestion is further made that it is "advisable to restrict its use to deposits formed along geologic shear-zones where the resulting water channels were so irregular that they can not be defined by any of the other terms already given." The writer has applied the name 'metallized shear' zone to a type of ore deposit very common in Sonora, and has several times discussed its characters in the columns of the MINING AND SCIENTIFIC PRESS. It is formed in a zone where the sheeting has been very close, the parallel fault-planes having an average interval of a few inches. This results in a mass of shattered rock, which differs from an ordinary fault breccia in that the rock fragments have not been materially displaced from their original position with reference to adjacent fragments. A fault breccia may, however, occur within the zone of shearing. Through this porous zone a metalliferous solution may readily flow and, under proper chemical conditions, metallic minerals may be deposited in the interstices of the breccia and within the rock fragments, the deposition being associated with varying degrees of replacement. Now these deposits are often as regular in form as any true vein, but the limits of the metallization are not always abrupt and the boundaries of the ore are only to be ascertained by assay. The type is unquestionably entitled to a distinct designation, and the name 'metallized shear zone' seems accurate and satisfactory. To say mineralized shear zone does not convey the same meaning, for a shear zone may be mineralized with silica and carry no metal.

Sheeting.—"The term 'sheeting' or 'sheeted zone'

may be used where the movement has resulted in parallel fissures that have left thin sheets of country rock between them." Obviously this type of fissuring, when the fissures are wide enough to permit the deposition of vein-matter, causes the formation of a lode as above defined.

True Fissure Vein.—Under this head, objection is made to the word fissure as pleonastic, and it is proposed to use, as a better term, the expression true vein. While the briefer form is preferable, it is probable that custom will long sanction the use of the old expression 'true fissure vein'.

Ore-shoot, Pay-shoot.—"An ore-shoot or pay-shoot is that part of a deposit which is rich enough to exploit." While this is often true, it is not always so. A shoot is often an expansion of a vein or of its metallization, and the vein may be rich enough to exploit for a considerable distance, the shoot or shoots being wider or richer portions of the orebody which offer larger inducements to the miner.

Contact Deposits.—"The term 'contact deposits' should be restricted to deposits which have been formed by contact metamorphism, and which carry the minerals characteristic of such action. Such use eliminates from this category many forms of deposit that have been so termed, simply because they happen to occur at the contact of two different kinds of rock, without regard to their origin. Contact deposits, as thus restricted, occur mostly in limestone, at or near its contact with an intrusive igneous rock." This restriction of the use of a familiar term leaves the miner without any convenient appellation for a very common sort of ore deposit. The plane or surface of contact between two different rock formations often affords a channel of flow for metalliferous solutions, and the resulting deposits are usually different from true veins, and deserve a generic name to indicate their type. It would seem as if scientific needs might be satisfied by selecting a specific name for deposits associated with contact metamorphism and leaving the older term, long in common use, for the general designation of ore deposits formed on planes of contact.

Impregnation.—"As a general rule, care should be taken to avoid using the name of a process as the definition of a type of deposit. The term 'impregnation', for instance, has been used by different writers in many and conflicting senses. It properly signifies the introduction of mineral substances in a finely disseminated condition into rocks, either as a filling of open spaces or as a replacement of certain minerals. To describe ore occurring in small, irregular, disconnected patches throughout the mass of a rock, 'disseminated deposits' is a preferable term, for it has no genetic signification." This statement does not seem to cover the whole ground. Minerals, such as sulphide ores, may primarily be disseminated through a rock and, by the alteration or decomposition of these disseminated mineral particles, the rock may be extensively impregnated.

Tunnel, Adit, and Drift.—These are defined according to custom, and the following additional distinctions are given: "An adit level and a drift are galleries running on the vein or in the strike of the

orebody; a tunnel is intended to cross-cut several veins or orebodies, and hence runs at an angle to their strike. A drift that runs at an angle to the strike is called a cross-cut drift or simply a cross-cut." The above statement of the purpose of a tunnel is somewhat unusual and limited, since it assumes the existence of more than one orebody and ignores tunnels driven for drainage or transportation.

Mine, Prospect.—"It may be difficult to decide whether a given property shall be called a mine or a prospect, and no hard and fast rule can be laid down to cover all cases." This statement has much truth, and might be commended to the attention of the Mining & Metallurgical Society of America for consideration in connection with the protection of investors. The author continues, "In general, shafts that are less than 100 ft. in depth, with less than 100 ft. of drifts, and that have not produced ore in commercial quantity, should be termed prospects. The essential feature of a mine is the production or presence of ore in marketable quantity, but the development and equipment of some unproductive properties are so extensive and complete as to warrant the application of the term 'mine', on the ground that it is less misleading than prospect." It is somewhat unusual to apply the term prospect to the shaft, rather than to the property in which the shaft is sunk, and the fact that a mine has produced in the past does not remove it from the category of prospects if the uncertainty of its future tonnage consigns it to that class of properties. The distinction between a prospect and a mine is partly expressed by saying that a prospect becomes a mine when enough ore has been blocked out to justify the erection of a reduction plant, but a mine that has been richly productive, if development is not kept well in advance of mining, may revert to the condition of a prospect, although not exhausted. Further, the author takes a position unsafe for investors, in considering that mere development work or equipment justify giving the name 'mine' to a prospect. The fashion of calling a deep hole in the ground, or a long tunnel, a mine has enabled unscrupulous promoters to swindle thousands of unsuspecting people. It may, of course, be unpopular with some owners of mineral properties to insist on a rigid definition of the word 'mine', but it is needed quite as much as a definition of the word 'ore'.

The staff of the United States Geological Survey in charge of Mining Geology has had so extended an experience in this field that it seems quite appropriate for that organization to prepare a glossary of terms used in describing mines and mineral properties, but such a glossary should be subjected to careful criticism in order to perfect the definitions adopted and make them harmonize, as far as possible, with established usage.

Nogales, Arizona, May 18.

Crucible Assays.

The Editor:

Sir—Relative to an article in your issue of June 12 under the heading 'Crucible Assays', by A. A. Steel, I desire to say that it may be very well to go into the theory of fluxes, and no doubt it is of ad-

vantage to anyone to have this knowledge. But to the slow process as outlined I must take exception, and I am sure that a great many other assayers doing custom work will join me. Where samples of ores for assay come in all sizes and shapes, some in a chunk, some in small kernels, and some ground to a pulp, the work would be much prolonged. In our office we use a flux composed of 60 parts sodium carbonate, 55 parts litharge, 15 parts borax, and with flour or nitre added to suit the ore. Of course the litharge may be reduced in the case of a rich lead-ore, or increased in the case of rich copper ores.

We have used a number of different fluxes, but find this the best mixture of all, and even in the case of complex ores we have no difficulty whatever. In the case of an ore with a lime gangue we add a little silica to keep the crucibles from being corroded, and also with ores which have little or no gangue material. In case I have not caught the real drift of Mr. Steel's article I would be pleased to hear more from him.

GEORGE DOYLE.

Osceola, Nevada, June 18.

Cost Sheet for Mines.

The Editor:

Sir—An article entitled 'Cost Sheet for Mines', by Algernon Del Mar, appears in your issue of June 5, that looks to me to be subject to criticism. He says, "estimate the mining cost on the number of tons mined, including the waste, etc." In my opinion, mine costs figured in this manner would be absolutely misleading; the amount of waste mined should not be considered at all. The object of keeping a record of costs is, primarily, to be able to tell whether or not there is a margin of profit, and what that profit is; in mining ores, if in mining one ton of ore the miner takes out a ton of waste, and then divides the cost of doing this work by two, he simply fools himself. If such a method of figuring mine-cost is correct, it is a simple matter for the manager to reduce his mining costs by merely breaking more waste. Again, under such a method, the cost of mining a small streak of ore could easily be made as low as the cost from large deposits; whereas, in all small-streak mines the mining cost must of necessity be high. Furthermore, if such methods were commonly used, the mining costs could be figured so low that prospective purchasers of a mine would imagine there was a liberal margin of profit in mining the ore, whereas actual experience would demonstrate that the ore itself was mined at a loss.

FREDERIC IRWIN.

Dewey, Idaho, June 11.

A Japanese-American electric apparatus manufacturing company has been formed. Information just published in the Japanese press discloses the fact that the Shibaura Works, managed by the Mitsui Co. and the Tokyo Electric Co., will be amalgamated and the General Electric will form a company with four million capital, controlled by the Americans. The General Electric owns a large tract of land at Kawasaki, and it is said that a large factory will be established there.—*Far Eastern Review*.

COMSTOCK BEGINNINGS.

Written for the MINING AND SCIENTIFIC PRESS
By JOSEPH T. GOODMAN.

Commemoration is a duty usually assigned to posterity, but the jubilee anniversary of the discovery of the Comstock will be celebrated the most spiritedly by the very men whose young blood was set astir by the event they commemorate. Their ranks will be thinner and their step less elastic than when they went to the front fifty years ago, but enough of the old guard and of the old spirit survives for them to make a brave and enthusiastic display on this memorable occasion. Of necessity, however, there will be something more than parading and rejoicing. When 'the tumult and the shouting' have died away it will be impossible for the veterans not to be as reminiscent as jubilant. And there will be so much scope for recollection! Little could they have

and the returns from the ore shipped to Swansea, it is doubtful if they would have been encouraged to continue development, for the initial arrastre, patio, and other processes of treating the ore at home, brought but poor results. The working of the mine also was conducted in such a primitive way that, in the light of present methods, it seems pitiable. For more than a year the ore from the Ophir and Mexican mines was brought up in rawhide buckets on the backs of Mexicans, who climbed steps cut in logs placed at an incline from level to level, and all the pumping was done by hand. But the indisputable richness of the ore had created widespread excitement, and every foot of the Comstock, and of the parallel veins, was not only quickly claimed, but doubly claimed in most instances, the locations generally overlapping if not actually overlying each other—a circumstance that gave rise to the expensive litigation in which the principal mining companies were involved for the

Virginia City, Looking South From Cedar Hill.

dreamed that the day of the discovery of that 'blue-black stuff' in Spanish ravine fifty years ago was a moment from which should date a history more wonderful than that of many an empire. Naturally their thoughts will travel back over that history, which itself now seems almost like a dream.

The beginning was so obscure and unnoteworthy—like the germ state of every kind of growth—and everything was so befogged by inexperience and ignorance. Some prospectors working in a ravine cut a mass of blue-black stuff whose character was to them a mystery. A specimen of it sent to California for assay proved it to be silver ore. That did not mean much to the average miner at the time, for few people on the coast knew anything about silver mining; and so distrustful were the discoverers of the value of a silver mine, even when informed of the richness of the ore, that they sold their claim for a mere pittance to capitalists who were willing to venture upon the experiment of working it. The outlook was not promising for these bolder men at the start. Had it not been for the remarkable assays,

first four or five years. Upon the wave of this excitement came the founders of Virginia City in such numbers that from its single saloon and boarding-house tent the place sprang into a town as if by magic. Of course not everybody was at once well housed. There was a brief era of tent and tunnel and almost every other kind of shelter. But the sound of construction was to be heard incessantly, until within three years there arose a city of imposing structures, with a population estimated at 30,000.

Virginia City was incorporated as early as February 1861—only a year and a half after the discovery of the Comstock. She already had an efficient fire department and police force, several churches and places of amusement, and the organization of public schools soon followed. That was quick work for even a frontier settlement. But the city was only keeping pace with the rapid progress being made in the development of the Comstock. The primitive style of mining at first in vogue had given place to a great hoisting works and pumping machinery; Deidesheimer had solved the problem of securely support-

ing the mines by square sets of timber; and it had been decided that it was more profitable to mill all the ore at home than to ship part of it abroad, even if there was a large percentage lost in treating it, and in consequence great reduction works were springing up in every direction. Activity was no longer confined to Spanish ravine, where the Ophir and Mexican works were situated. The Central, Gould & Curry, Savage, Hale & Norcross, Potosi, Chollar—in short, nearly every company on the lode—were getting under way, and some of them on a scale more extensive than had even been dreamed of before. The Comstock and Virginia City had fairly entered upon their marvelous career.

In the full tide into which that career swelled and swept on for years, the eastern slope of Mt. Davidson was the busiest and most picturesque sight ever seen. Immense hoisting works studded the mountain-side for miles, with their huge dump-piles and capacious ore-bins; quartz-mills were thundering and grinding in every available nook of the neighboring canyons; a continuous line of many-mule teams, hauling ore, wood, and merchandise, constantly crowded the streets and outlying roads; and in the town itself were such throngs of people as one would expect to encounter only in the heart of a great metropolis. The scene was made doubly animate by the prevalence of hope and high spirits. Everyone had money, or felt rich from the ease with which money was to be acquired; and all met on an equal footing, for the under one today might be at the top tomorrow. There was a deal of drinking, gambling, shooting, and other indulgences not looked upon with favor in a well-regulated state of society. But, upon the whole, the community was a surprisingly law-abiding one.

Under this careless surface life, as beneath the very ground on which the city stood, a mighty force was ceaselessly at work, with an earnest spirit and purpose. Nevada seems to have been predestined for two great missions. Her organization as a Territory, in 1861, and her admission as a State, in 1864, before she had population enough to entitle her to a single member of Congress, were both essentially war measures; hence she is justly proud of her distinctive title of the 'Battle Born'. The Government needed the assistance of her loyal people in the legislation necessary for the preservation of the Union, and right loyally it was given, together with aid by every other means in her power. In proportion to her population, Nevada sent more men to the ranks and contributed more money to the Sanitary fund than any other Territory or State; she was the first to ratify the Constitutional Amendments that secured the fruits of the war and cleared the way for reconstruction; and the output of treasure from her mines was a principal factor in sustaining the national credit. The importance of that product, in the estimation of the greatest and wisest statesman of that time, is shown by the words of Abraham Lincoln on two occasions: "I am glad to see you here," was his first greeting to Senator Stewart; "we need as many loyal States as we can get; and, in addition to that, the gold and silver in the region you represent has made it possible for the Government to maintain sufficient credit to continue this terrible war for the Union."

And the very day he was assassinated he requested Speaker Colfax, who was about to visit the Pacific States, to carry a message from him to the miners. "Tell them," said Mr. Lincoln, "that during the war, when we were adding a couple of million dollars a day to our national debt, I did not care about encouraging an increase in the volume of our precious metals; we had the country to save first; but now that the rebellion is overthrown and we know pretty nearly the amount of our national debt, the more gold and silver we mine will make the payment of that debt so much the easier." True to the expectation and trust of the martyred President, Nevada has never ceased pouring out a stream of treasure to aid the Nation and enrich the world, though in her munificence the generous State has left herself comparatively poor.

A mission of almost as much importance, and as faithfully performed, was the guidance the Comstock was destined to give to the mining industry of the world. The experience gained in working that lode revolutionized mining on a large scale, and practically created the science as it is known today. From every quarter of the globe where extensive operations have been projected a demand has come, and is still coming, for engineers and workmen skilled or schooled in the methods and machinery of the Comstock. There is a significant promise in the fact that for fifty years the great lode has pioneered the way for others to follow. The genius and determination that overcame every obstacle in the past should be equal to the problems of the present and the future, hence it is only reasonable to hope that the mission of the Comstock will not be entirely fulfilled until an example is set of successful silver mining at a depth never before attained.

The restrictions of time and space preclude anything like a full review of the past fifty years of the Comstock and Virginia City—the fluctuations in the fortunes of the mines, the vicissitudes in the life of the town, the changes wrought by the railroad, the great Sierra water-system, and the introduction of electric power—but even a cursory notice would be incomplete without mention of some of the men whose names will remain most closely connected with their history. In that regard, precedence should probably be given to those who controlled the mines, and thereby to a great extent shaped the destinies of the lode and the community. The first of these, in point of time as well as of executive ability, was William Sharon. He went to Virginia City in 1863 to establish a branch of the Bank of California. The bank and the capitalists associated with it already controlled the principal mines, and Sharon soon devised a way by which he and a few others became the owners of a majority of the mills as well. Quite a number of men had built what are termed 'custom-mills', that is, they had no mines of their own, but worked ore for any company that would furnish it. Most of them, however, had involved themselves and were in need of financial aid, and Sharon, as manager of the branch bank, generously came to their assistance. But no sooner had they secured a loan than their supply of ore was cut off, and as a matter of course their mills in due time fell into the hands

of the bank. These properties, however, did not go into the assets of the bank for the benefit of its stockholders. They were taken out by Mr. Sharon and his friends and organized into the Union Mill & Mining Co., which thenceforward became an instrument for absorbing the wealth of the Comstock mines. If a mine had a rich body of ore, more than an equal share of waste rock was mixed with it to feed the insatiable maw of the great milling company; if the ore was poor, the stockholders were assessed to make up the deficit in the cost of reduction.

Such was the general condition of things under the Sharon régime, relieved only by a few companies which independently managed their own affairs, notably the Crown Point, that under the control of Alvinza Hayward and John P. Jones developed one of the greatest bonanzas in the history of the Comstock. But two comparatively obscure men, John W. Mackay and James G. Fair, both practical miners, and familiar with every inch of the lode, had quietly been getting a line on matters, and in conjunction with James C. Flood and William S. O'Brien, of San Francisco, they wrested the control of Hale & Norcross from Mr. Sharon and his friends, in 1868, and quickly turned it from an assessment to a dividend-

Divide From Wheeler Monument.

paying mine. That was the first appearance of the great Bonanza firm upon the scene; but their uncovering of the immense orebody in the Consolidated Virginia and California a few years afterward, and the enormous fortunes realized from it, thenceforth left them undisputed masters of the Comstock, until death or voluntary retirement put an end to their reign. It would be difficult to say if in the long run stockholders fared better under any one of these managements than under the others.

Probably the lawyers constituted the next most noteworthy class of men in the early history of the Comstock. It has been estimated that \$10,000,000 was the cost of litigation within five years from the discovery of the lode. That implies either an extraordinary quantity or quality of legal talent, and Virginia City had both. There was scarcely a California lawyer of prominence who did not establish himself there or form a partnership through which his services might be enlisted in the great mining cases. It would be invidious to cite a few out of a list of more than a hundred, but there was one who deserves particular mention, William M. Stewart. Not that he was superior to many others in professional ability, but his force and integrity of character inspired a confidence that raised him to the position of legal

representative of all the Comstock mining companies, and it was by his efforts that the rules and regulations of the miners were crystallized into statutory form and became the law of the land. Nor is this all for which Nevada is indebted to Senator Stewart. It was through his untiring zeal and energy that she acquired her enlarged boundaries; that by the exchange of the worthless sixteenth and thirty-sixth sections for valuable lands she was endowed with her magnificent school fund; that the land-grant and annual appropriation were obtained for the support of the State University and the Agricultural Experiment Station; and that the Government provided for the establishment and maintenance of the Indian school at Carson. Not only the miners of Nevada, but the people of whatever occupation, owe more to the late William M. Stewart than to any other man who ever lived in their State; and it would be a crowning act of this memorial occasion to take some step toward erecting a worthy monument to his memory.

Of less influence in their day than any of those mentioned, but of more importance in perpetuating the fame of the city and the lode, were two young men employed in the humble capacity of reporting for one of the daily papers, the *Territorial Enterprise*. The name of one, Samuel L. Clemens, or Mark Twain, is now the foremost in the world of literature. That of the other, William Wright, or Dan de Quille, is scarcely known away from the Pacific Coast, but of the two he performed the greater service for Virginia City and the Comstock. Mr. Clemens came on the scene in 1862, and remained until 1864, a period just covering the palmiest days and the most riotous life in the history of Virginia City. He was then only a literary beginner, and it was there that he assumed the pen-name he has made immortal. The reckless, rollicking, tragical sights he daily witnessed thrilled every nerve in him and schooled him into that irreverent and humorous way of dealing with facts, and that scorn for sham, which have been his stock in trade ever since. He has never pretended to write an accurate account of his sojourn on the Comstock, but so thoroughly impressed was he by his experience there that in 'Roughing It' he has caught the spirit of the tumultuous, graceless life of those early days, and has given a better presentation of it than any one who has ever attempted to reproduce it. Dan de Quille was a more matter-of-fact and plodding man than Mark Twain, though possessing quite as rich a gift of humor. He was acquainted with the Comstock almost from the date of its discovery, and probably there was never another man in Nevada who had so exact a knowledge, and who kept so close an account of the condition of every mine on the lode, as he did for more than twenty-five years. He was an unusually keen observer of persons and incidents and everything else that came within his range of vision, and he had moreover a wonderfully retentive memory. The store of information acquired by him in the course of time was embodied in his book, 'The Big Bonanza', the completest account of the Comstock lode and Virginia City ever written, and a work that will forever remain the great repository of facts relating to them.

DISCOVERY OF THE GREAT COMSTOCK MINE.

By DAN DE QUILLE.

*In the spring of 1859 Peter O'Riley and Pat McLaughlin set to work well up at the head of Six Mile canyon near Gold Hill. They used rockers and found small pay. They continued to work at this point until June 1, 1859, gradually extending their operations up the slope of the hill. They had started a little cut or trench and were washing the dirt taken from this in their rockers. Before they started the cut they were making only from \$1.50 to \$2 per day; in the cut their pay was even less. They were becoming discouraged, and were thinking of going to Walker river to try their luck, but concluded to work on where they were a few days longer.

Having but a small stream of water, it became necessary for them to dig a hole as a sort of reservoir, in which to collect it for use in their rockers. They set to work a short distance above to make the water-hole, and at a depth of about four feet struck into a stratum of the rich decomposed ore of the Ophir mine, and of the now world-famous Comstock silver lode. What they found was not glittering native silver, but a great bed of black sulphuret of silver—a decomposed ore of silver filled with spangles of native gold. This gold, however, was alloyed with silver to such an extent that it was more the color of silver than of gold. The gold dug in the placer-mines of California is worth from \$16 to \$19 per ounce, whereas the gold taken from the croppings of the Comstock was worth no more than \$11 or \$12.

When the discoverers struck into the odd-looking black dirt, they only thought that it was a sudden and rather singular change from the yellowish gravel and clay in which they had been digging. As any change was welcome, they at once concluded to try some of the curious-looking stuff in their rockers. The result astounded them. Before, they had only been taking out a dollar or two per day, but now they found the bottoms of the rockers covered with gold as soon as a few buckets of the new dirt had been washed. They found that they were literally taking out gold by the pound. However, as the gold they were getting was much lighter in color and weight than any they had found below in the canyon, or even on the surface in their cut, they began to fear that all was not right. They thought that, after all, what they had found might be some sort of 'bogus stuff'—base metal of some new and strange kind. It is not strange that these impecunious miners, tinkering away there on the side of a lone, sage-covered mountain, with their rockers, should have felt a little alarmed on account of the great quantity of gold they were getting, as in a few weeks after the discovery had been made they were taking out gold at the rate of \$1000 per day. This they were doing with rockers. Taking the harder lumps left on the screens, one man was able to pound out gold at the rate of \$100 per day in a common hand-mortar.

In the evening of the day on which the grand discovery was made by O'Riley and McLaughlin, H. T.

P. Comstock made his appearance upon the scene. 'Old Pancake', who was then looking after his Gold Hill mines, which were beginning to yield largely, had strolled northward up the mountain, toward evening, in search of a mustang pony that he had out prospecting for a living among the hills. He had found his pony, had mounted him, and with his long legs dragging the tops of the sage-brush, came riding up just as the lucky miners were making the last clean-up of their rockers for the day. Comstock, who had a keen eye for all that was going on in the way of mining in any place he might visit, saw at a glance the unusual quantity of gold that was in sight. He was off the back of his pony in an instant and down in the thick of it all—'hefting' and running his fingers through the gold, and picking into and probing the mass of strange-looking 'stuff' exposed. Conceiving at once that a wonderful discovery of some kind had been made, Old Pancake straightened himself up, from a critical examination of the black mass in the cut, and coolly proceeded to inform the miners that they were working on ground that belonged to him. He asserted that he had some time before taken up 160 acres of land at this point, for a ranch; also that he owned the water they were using in mining, it being from the Caldwell spring, in what was afterward known as Spanish ravine.

Suspecting that they were working in a decomposed quartz vein, McLaughlin and O'Riley had written out and posted up a notice, calling for a claim of 300 ft. for each and a third claim for the discovery; which extra claim they were entitled to under the mining laws. Having soon ascertained all this from the mine before him, Comstock would have 'none of it'. He boisterously declared that they should not work there at all, unless they would agree to locate himself and his friend Manny (Emmanuel) Penrod in the claim. In case he and Penrod were given an interest, there should be no further trouble about the ground. After consulting together, the discoverers concluded that, rather than have a great row about the matter, they would put the names of Comstock and Penrod in their notice of location. This being arranged to his satisfaction, Comstock next demanded that 100 ft. of ground on the lead should be segregated and given to Penrod and himself for the right to the water they were using—he stoutly asserting that he not only owned the land, but also the water, and, as they had recognized his right to the land, they could not consistently ignore his claim to the water flowing upon it. In short, he talked so loudly and so much about his water-right that he at last got the 100 ft., segregated, as he demanded. This 100 ft. afterward became the Spanish or Mexican mine, and yielded millions of dollars.

Comstock would probably not so easily have obtained what he demanded, had the men who made the discovery been fully aware of its great value. They, however, did not know that the 'blue stuff' (sulphuret of silver), which they had dug into, was of any value, and even the gold itself seemed altogether too plentiful as well as a good deal 'off color'. Comstock had probably at some time posted up a notice claiming 160 acres of land, somewhere in that neighborhood, as a ranch, but if he did so he never had his

*From 'The Great Bonanza', by Dan De Quille (Wm. Wright), 1876.

notice recorded. Men in those days, while roving about the country, frequently wrote out and stuck up notices claiming land, springs, the water of streams, quartz veins, gravel deposits, or anything else that they might for the moment think valuable, but unless such claims were properly recorded and worked they could not be held, as all miners and others well knew—a mere notice expiring at the end of 10 days, when the property might be taken up, recorded and held by the first man that came along. Comstock had some show of right to the water and to the placer-mines along the upper part of Six Mile canyon, as the year before, he, Old Virginia, and Penrod had bought of old Joe Caldwell a set of sluice-boxes and the water of a spring. However, the possession of a set of sluices on the canyon and a right to use water from a certain spring in the neighborhood, by no means gave Comstock or his friends the right to lay claim to a vein of quartz found in a hill somewhere in their section of the country.

John Bishop, who bought Old Virginia's interest in the sluices, gravel-diggings, and water, got no share of the quartz vein discovered by Pete O'Riley and Pat McLaughlin, though he managed to get in on the lead, locating the mine known as the Central No. 1; now a part of the California, one of the bonanza mines with millions of ore in sight. Bishop put up the first arrastre ever built on the lode, starting it up two or three days before that of the Ophir began running. He sold his interest in the Central No. 1 for \$4000, and shortly afterward the purchasers sold the same ground for \$1800 per foot—now (as incorporated in the California mine) the ground is selling at over \$50,000 per foot, and John Bishop still works, as a miner, at Gold Hill.

After Comstock had managed to become largely interested in the new discovery, and after the gold taken out by O'Riley and McLaughlin had been carried down to Gold Hill and exhibited and examined, there was at once a great local excitement in regard to the new diggings, and all were anxious to get an interest in the claim, or on the lead as near to the original discovery as possible. Those who were finally recorded in the Ophir notice as original locators were the following persons: Peter O'Riley, Patrick McLaughlin, H. T. P. Comstock, E. Penrod, and J. A. ('Kentuck') Osborne. The men named had one-sixth each of 1400 ft. of ground on the lead and, in addition, Comstock and Penrod had 100 ft. segregated to them, making 1500 ft. taken up by the party. The 100 ft. of Comstock and Penrod, though in the midst of the 1400 ft. of ground, was not reckoned as a part of the Ophir claim and was soon sold and worked as a separate mine, under the name of the Mexican or Spanish mine. The Ophir claim was the first that was located, as a quartz claim, at any point on the Comstock lode, though as early as February 22, 1858, Old Virginia (James Finney or Fennimore) made a location on a large vein lying to the westward of the Comstock. This vein is known as the Virginia lead or Virginia croppings. It has never yielded much ore, but contains vast quantities of base metal of various kinds. At one time it was thought by some that this would prove to be the main or 'mother' lead of the range, as at the surface, and for

a considerable distance below the surface, the Comstock vein dipped west toward it. Parties bought Old Virginia's claim, and began suit against the Ophir company, asserting that the lead on which they were at work was the same as that located, in 1858, by Old Virginia. It was a sort of speculation on the part of those who brought the suit, and it is understood that they succeeded in obtaining \$60,000 from the Ophir company. At the beginning of this suit it was necessary, if possible, to produce the original notice placed upon the croppings of the lead by Old Virginia, but the parties to whom he had sold his claim could never get him sufficiently sobered up to show where it could be found. Growing desperate, they at length seized the old fellow one evening, and thrusting him into the mouth of a big tunnel, closed and locked upon him a heavy iron gate. The next morning when they went to the tunnel they found Old Virginia sober, but very savage. He would say nor do nothing until they had taken him down town and given him half a tumbler of whiskey. This swallowed, he was ready for business. He marched directly up the side of the mountain, and going straight to a large tower of croppings, drew out a small block of rock, and lo! behind it was seen snugly stowed the much-desired notice.

It was probably on account of his having made this location that Old Virginia was given the credit of having been the discoverer of the Comstock lode, his interest in which he was said to have sold for an old horse, a pair of blankets, and a bottle of whiskey. He sold a third interest in the sluices, water, and diggings in the canyon to John Bishop, for \$25. James Hart, who had an interest in the sluices, and diggings in the canyon, sold his right to be 'considered in' on the big discovery to J. D. Winter, of Washoe Valley, for a horse and \$20 in coin.

MINERAL DEPOSITS IN FIJI.

Prospects of future importance as a mineral producer are apparently turning the thoughts of the colonists of Fiji from the production of copra and sugar cane. There seems to be some doubt yet as to what the mineral deposits actually consist of, but reports are to the effect that copper, gold, and silver have been found. The existence of tin is also suggested. The assay returns of a 15-ton parcel sent to Sydney for treatment, it is said, gave a valuation of 40% copper and $2\frac{1}{2}$ oz. of gold, with a certain amount of silver. To what extent this result is to be relied upon, and what is the bulk of the deposits of this richness are matters too risky to forecast, but it can be safely prophesied that, if there is much of such ore, the copra and sugar cane growing industries will soon be relegated to places of minor importance. The prospects of the colony from the mining man's point of view have at least drawn the attention of Western Australian mining men, and The Fiji Prospecting & Option Syndicate has been formed to verify or refute the statements as to the mineral wealth of this portion of the South Sea Islands. Several Western Australian mining men are responsible for the formation of this pioneer venture, and they are now in Fiji.—*Australian Mining and Engineering Review.*

THE COMSTOCK MINES TODAY.

Written for the MINING AND SCIENTIFIC PRESS
By WHITMAN SYMMES.

It is just fifty years ago since a few placer miners, working up the gulches from the Carson river, found their 'pay' stop at the outcrop of the Comstock Lode. During that time mining on the lode has swung through a complete cycle, and its semi-centennial witnesses the fact that deep mining is being re-established, and along successful lines. It is interesting to note that one of the little party of the lode's discoverers, E. Penrod, is still alive and still a mining man, and that he will leave his claims in Mono county to attend the Comstock Golden Jubilee.

The policy that is now being pursued in unwatering the mines is radically different from that followed

plishes a double purpose. A drift that is dry can soon be cooled by ventilation, but when steaming water is dripping from the roof of the drift it brings in so much heat that a proper reduction of temperature is impossible, even though the 'snowshed' method of lining the drift be adopted. A year ago the 2250-ft. level of the Consolidated Virginia was hot and steaming, but since the 2350-ft. level has been run beneath, it has become a cool drift, and its 'snowsheds' are no longer kept in repair. The method of exploring coincidentally with complete drainage has already brought important results. In the first attempt at exploration of the deeper levels of the north end it was repeatedly announced in the reports that the drifts were kept to the west for fear of encountering too much water. It is now proved that those drifts were also kept too far west to penetrate the

Ophir

Union Con. Va.

C. & C. Shaft

Virginia City From the Outcrop of Comstock Lode.

in the early eighties. The pumping plants at that time being insufficient to completely unwater the lower levels, it became customary to bulkhead the wet drifts, plug the diamond-drill holes that had struck water-seams, and confine exploration to the drier portions of the lode. This method was, of course, doubly disastrous. Not only did the miners have to retreat from those areas that were wet, and therefore fissured and most likely to contain ore, but the water that was held back by the bulkheads soon found its way to the levels below, whence it required more power to lift it to the surface. The pressure of the water above also increased the liability to the sudden 'rushes' that so frequently overwhelmed the pumps.

The opposite policy has now been adopted. The lode will be drained, level by level, in advance of the exploration for orebodies. Complete drainage accom-

plishes a double purpose. Since 1903, when the water at the C. & C. shaft was first lowered sufficiently, several million dollars have been extracted from the Consolidated Virginia and Ophir mines between the 1900 and 2300-ft. levels.

Thus far the only area to be drained is that adjacent to the C. & C. shaft, at the north end of the lode. The Ward shaft has reached a depth of 2560 ft., and a drift now being started on the 2450-ft. level will ultimately be connected with the Combination shaft, and will thus drain all of the middle mines to that depth. It is intended to begin the drainage of the southern portion of the lode as soon as the principal Gold Hill mine-workings are cleared as far down as the Sutro Tunnel level. This will be at no distant date.

At the north end the water now stands a few feet below the 2450-ft. level, corresponding to the 2300-ft.

level in the Ophir. Everything is on hand to take the water down to the 2650-ft. station, which is the bottom of the shaft. A 30-in. wooden-stave pipe is being installed in the Sutro Tunnel to carry the drainage from the mines, and more than half of it is already in place. As soon as this is completed, it is intended to begin sinking in the C. & C. shaft, instead of opening up the levels below that point by a complicated series of winzes, as was formerly done. The fire in the Sutro Tunnel last January was a great misfor-

now being energetically prospected. Also the Bulion, Chollar, Potosi, Julia, Hale & Norcross, and the Savage will at no distant date be enabled to resume deep-level exploration from the 2450-ft. drift which is now starting from the Ward shaft. The upper levels of the Gold Hill mines are being re-opened, and the Crown Point is now being explored on the 1100, and the Yellow Jacket on the 1200-ft. level. The Yellow Jacket mill is working the so-called 'gold ledge' and is today extracting about 80% from a \$6 ore by

Butters Cyanide Mill.

Ward Shaft.

tune to the mines, as it not only entailed a heavy expense, but also delayed the installation of this pipe. Therefore the further lowering of the water at the north end was also delayed. The mine-water is now lifted to the Riedler pumps on the 2150-ft. level of the C. & C. shaft by means of a jet-pump, and the cold pressure-water from the Virginia & Gold Hill Water Co.'s ditch serves to lower the temperature of the mine-water, with which it mingles. When the stave-

concentration alone. The principal Gold Hill mines are now so nearly able to pay expenses that their manager, George S. Sturges, has hopes of getting them upon a self-sustaining basis as low-grade properties. The water-level is between the 1400 and 1500-ft. levels, and considerable low-grade ore is believed to remain on upper levels. No work has been done below the 1400-ft. level in Gold Hill since the flood of 1882. The best producer on the lode is still the

Ophir. During the past year the milling ore has averaged about \$30 per ton, and the shipping ore \$80. About one-half the value is in gold, and the other half in silver. Charles Butters & Co., Ltd., have leases on the upper levels of the Chollar and Potosi mines. They are extracting ore by ordinary mining methods and by means of 'glory holes' along the outcrop. As they pay royalties on ore assaying as low as \$4 per ton, it is believed that they can mine, transport the ore two miles by aerial tramway, and cyanide it in their mill for about \$3.50 per ton. They are undoubtedly now mining and cyaniding a gold-silver ore at a lower cost than any other company in the State of Nevada. At present the Chollar and Potosi

Interior of California Pan Mill.

pipe is finished, it will be possible to pump direct from the sump to the Sutro Tunnel. If this were now done, the hot water, flowing through the tunnel in the open, would so heat it as to make necessary repairs impossible. The Ward shaft is now sinking through a 'pocket' of hot water of 163° F., and is pumping direct to the tunnel without mixing its drainage with cooling-water. At present it affords only about 300 gal. per minute, against the 2300 gal. of hot water that is coming from the C. & C. shaft.

A year ago no miners were employed in active exploration for ore in the Mexican, Crown Point, or Belcher. At these important old mines the ground is

outcrop affords them about 200 tons per day, which amount will soon be largely increased. They are also milling ore from the Ophir and the Consolidated Virginia mines. In the bonanza days at the Comstock pan-amalgamation was developed, and reached there a state of perfection which won it world-wide acceptance for the treatment of ores rich in silver sulphides. It was known as the Washoe process, in consequence of its Nevada origin. In effect it was an adaptation of the old patio process of Mexico. Instead of waiting for the slow reactions occurring in a *torta* or mass of pulp containing silver sulphide, to which copper sulphate and salt have been added, the

mass is ground and agitated in a grinding-pan, the reactions being hastened by the injection of live steam. Thus the work which required two weeks in the patio was accomplished in several hours in the pan. The process is now being superseded everywhere by cyanidation, and it will soon become interesting only to the metallurgic antiquary. The interior of one of the old Comstock mills, the California, is shown in the accompanying illustration.

The Ward shaft pumping plant is designed to be the largest of any precious metal mine in the United States. One 800-hp. unit now temporarily installed on the 2475-ft. station is direct-connected to an electric motor and runs at a speed of 196 revolutions, or 523 ft. of plunger speed per minute. The behavior of this pump in a long test by practical operation will have an important effect upon the future design of large electrically driven mine pumps in this country.

During the past few years a great deal of necessary 'dead work' has been accomplished. The men on the Comstock believe that the fiftieth anniversary of the discovery of the lode marks also the date of its substantial rehabilitation, and that the mechanical and metallurgical improvements which have lately been made there will enable the miners of today to work the low-grade ores and to explore in search of bonanzas those portions of the lode which the men of thirty years ago were unable to enter.

JEFFERSON CANYON, NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE A. PACKARD.

In Nye county, Nevada, five miles easterly from the new camp of Round Mountain, and 50 miles north of Tonopah in an air-line, is the old camp of Jefferson. For nearly forty years the stage from Austin to Belmont followed the road up Jefferson creek from the Big Smoky valley to the summit of the Toquima range, but after the opening of the mines of Manhattan and the discovery of Round Mountain, the route was changed, and a detour made to the south to include these places. During the seventies several mines were worked in Jefferson canyon, which was then known as the Concordia or Green Isle mining district. The largest producers were the Jefferson and the Prussian companies, owning adjoining claims, the Prussian South and Prussian, on the same lode. This vein has a northwest strike, with a dip to the northeast of about fifty degrees, and has been traced for several thousand feet. It lies between a porphyry hanging wall and a slate foot-wall, though the occurrence of slate is limited. To the southwest quartzite may be seen overlying limestone, and this in turn lies upon granite. In passing up Jefferson canyon this hanging wall porphyry shows two rocks quite unlike in appearance, one a very light brown, the other gray in color. Microscopic examination of slides shows, however, that these are not materially different. Both may be termed rhyolite, and show a strongly marked flow-structure, as does the country rock at Round Mountain, which they closely resemble. The darker shows, with the high powers, a ground-mass, once glassy, of indistinct crystals crowded with decomposition products

such as kaolin and calcite. The quartz phenocrysts, which are fairly abundant, are large, and are generally somewhat rounded crystals. More abundant than these are the crystals of albite, now largely replaced by calcite. The rock also shows orthoclase, biotite altered to chlorite, and grains of magnetite. The ground-mass of the lighter rock is similar to that of the darker, except that it is more discolored with ferruginous matter, which also appears in the phenocrysts. There is somewhat less calcite.

Alexander Trippel, reporting on the Jefferson and Prussian properties in 1881, says: "It has been stated that the two mills shipped a million dollars worth of bullion; for the absolute truth of this statement I cannot vouch, but to my own personal knowledge \$200,000 worth was produced during one year. Both companies worked their mines by means of inclined shafts sunk on the vein, the Jefferson company to the depth of 700 ft., and the Prussian to the depth of 250. The width of the vein varied from 2 to 7 ft., with a smooth and regular wall on either side. The ore was not uniformly distributed, but was found in obliquely inclined chimneys several hundred feet in length, between which the vein was either low grade or barren." These properties have not been worked since 1876, except for a short time by lessees. Apparently they were closed because in depth the amount of water increased and the ores became too 'base' to work by methods then known. The ore in this vein contained silver chiefly, and at water-level sulphides and sulphantimonides were found.* In the hanging wall porphyry are a number of veins which have been held and worked by a single miner for over thirty years. Some of these parallel the Prussian vein, but others are apparently nearly at right angles. In doing some 4000 ft. of work, ore yielding many thousand dollars has been sorted and shipped, but the bulk of the ore is comparatively low grade. Recently two New York men have acquired control of this property, and are erecting a mill. This ore differs from the ore of the Prussian contact-vein in that it carries more gold than silver, though the proportion of silver is larger than in the ore occurring in the similar porphyry at Round Mountain. There is also some work being done to the southwest of the Prussian vein, on the contact of the granite and sedimentaries.

Wireless stations are to be erected in the interior of China. The difficulty of establishing communication by telegraph across the deserts between Peking and the extreme northwest of the Empire is to be surmounted by the installation of an extensive wireless system under the control of the Chinese Government. The Board of Posts and Communications is now making investigations as to the best system to adopt.—*Far Eastern Review*.

The lower limit of manganese steel is determined by the fact that alloys between 7½ and 5½% of manganese are weak and brittle. The characteristic strength and toughness can only be given to steels having more than 8 per cent.

*Mineral Resources of the United States, 1875, p. 281, and 1876, p. 138.

COMSTOCK DRAINAGE PROBLEMS.

Written for the MINING AND SCIENTIFIC PRESS
By LEON M. HALL.

The first mining of any magnitude on the Comstock was upon the orebodies adjacent to the surface or embraced directly within the outcrop of the vein.

Consolidated Virginia Shaft.

From the surface the lode paid handsomely, and the early development brought forth the great bonanzas. These were enormously rich and of large extent, but they were soon denuded of the masses that could pay by the crude methods then in vogue. Between these orebodies and the deposits unearthed in the Bonanza mines, the Belcher and Crown Point, there was a zone of barren or low-grade quartz, which is usually the case in all gold and silver lodes. The second line of bonanzas has been practically exhausted; at any rate, down to the depth of the Sutro Tunnel. When operations were discontinued, the workings were in the second zone of barren quartz, and while no rich bonan-

Pumping Engine, Yellow Jacket.

zas were then in sight, there were no discouraging features developed; on the contrary, in many parts the prospect was bright. The indications in both the Hale & Norcross and the Belcher pointed to a large deposit at no great depth below the workings at that time. The Yellow Jacket (Taylor shaft) passed through the vein at about the 3000-ft. level, and here the foot and hanging walls were 60 ft. apart,

with an unusually promising body of quartz between them.

It was about this time (February 13, 1882) that an immense reservoir of exceedingly hot water was encountered on the 2700-ft. level of the Exchequer. This was of such volume that the appliances then extant were entirely inadequate to handle the river that was pouring into the Gold Hill mines. In the middle and north-end mines the state of affairs was different. New shafts had been sunk to the east of the second line of workings, and a vast amount of prospecting was being done, when orders came to abandon deeper mining and to return to the ore left behind, in the search for new and possibly vaster deposits. At the time when work was discontinued in the deep shafts and a return was made to operating the upper levels, the Combination shaft, then one of the deepest vertical shafts in the world, had reached a depth of 3250 ft., and the Yellow Jacket a depth of 3000, the Sutro Tunnel intersecting the former at a depth of 1590 ft. and the latter at about 1513 below the

Head-Frame, 80 Ft. High, Forman Shaft.

surface. A similar ratio existed in all of the deeper mines. Thus, with the advent of the Sutro Tunnel, a new and lower working-surface was created, and the depth for operating was virtually reduced about 1500 ft., making it possible to sink to the 3000-ft. from this level with the same facility as was formerly done from the surface.

During this period all of the principal shafts on the Comstock were equipped with magnificent hoisting plants, some of which were capable of operating to a depth of 4000 ft. Among the most notable may be mentioned the large first-motion engines that were installed at the Yellow Jacket and Union shafts. These hoists consisted of double 30 by 96-in. engines, equipped with

flat-rope reels and a flat rope 8 in. wide. They were capable of making the trip from the 3000-ft. level with a load of 10 tons in one minute. At many of the other shafts large geared hoists were installed, which, together with numerous large air-compressors and the attendant necessary boiler-plants, made an imposing equipment. At several of the more important shafts it was not an uncommon

occurrence to consume 60 cords of wood per day.

Nearly 20 years have now elapsed since most of the largest mining plants for the Comstock were planned and installed. Criticism of the past from the standpoint of today, with the experience and advancement made in all pumping appliances before us, is liable to be harsh and unjust. The defects are readily seen, while the causes that led to them are forgotten. Furthermore, nearly every system as planned in practice falls short of its calculated efficiencies, and is handicapped and confused by the multiplicity of commercial interests involved, and no mining district has had greater difficulties to contend with in pumping than were met by the engineers on the Comstock Lode.

The completion of the Sutro Tunnel, and its employment for drainage purposes by the several companies, changed nearly the whole system of pumps as originally designed. The costly and massive pumping engines were left on the surface, while all intervening pumps were removed to below the tunnel-level, where they were doubled up, two being placed at each tank-station. This change left about 1700 ft. of heavy pump-rods between the surface engine and the first set of pumps. Double the work was being done on the lower end of the rods that was originally intended, and the fibres of the rods became fatigued and over-strained. Velocity diagrams taken from the pump-rods underground showed that their motion was not regular or uniform with the surface engines. The effect of the elasticity, and the great length of the rods, produced accelerations and consequent strains that many times exceeded the direct strain due to pumping alone. In the case of the Ophir rod at the 2400-ft. level, strains were found that exceeded the proper one by over nine times. The cause for the constant need of renewing pump-rods, broken balance-bobs, pins, and strapping plates, that was almost a weekly occurrence, was thus made apparent. As for the remedy, there was none with that class of pumps and machinery, necessarily placed at such a great distance from the water to be pumped.

For the benefit of those not familiar with the magnitude and the extent of the pumping plants erected and operated on the Comstock up to the year 1886, a brief description is here given, as it will enable them to better understand the reasons for some of the enormous expenditures in pumping in the past, compared with what is being accomplished at the present time. The Mexican-Union pumping engine was originally built in Europe as an overhead-beam Cornish engine. It was brought over, re-built, and changed to the compound condensing fly-wheel type. The cylinders were placed over the main beam, and inclined to each other with their connecting rods attached to the beam, one on each side of the beam-centre. The pump-rod was connected at the pit end, and the connecting rod of the fly-wheel at the other. The fly-wheel was 36 ft. diam, and weighed, with the shaft, 208,700 lb. The wrought-iron beam under the cylinders was 22 ft. long between the pump and the fly-wheel pins, and weighed, when completed with braces, 238,610 lb. The high-pressure cylinder had a diameter of 64 in. and a stroke of 6 ft. 9 in. The low-pressure cylinder was 100 in. diam and 8 ft. 6 in.

stroke. The air-pump was single-acting, 54 in. diam. and 6-ft. stroke. The nominal stroke of the pump was 10 ft. The engine was first started in April 1880, with a double line of 14-in. plunger-pumps discharging into the Sutro Tunnel. In January 1883 the 14-in. pumps were replaced by 10 plungers 17 in. diam. In making this change a thousand feet of new 18-in. pump-rods, with extra strapping plates, were put in. The pump-rod, from the surface-bob to the 2700-ft. level, was 2618 ft. long, and was counterbalanced by means of nine balance-bobs, with from 18 to 20 tons in each bob. The total weight in motion while pumping was 1,620,500 lb., or about 620 lb. for every foot of pump-rod. The total lift from the pump at the 2700-ft. station to the lateral drift of the Sutro Tunnel was 1180 ft. On account of the great length, elasticity, and weight of the pump-rod, the actual strokes of the plungers averaged by measurement 9.7 ft., when the surface stroke was 10 ft. A similar loss of stroke was noticed on all the Cornish pumps in use on the Comstock.

The hydraulic system installed and started at the Combination shaft in May 1881 consisted of a surface pumping engine, compound-condensing type, with horizontal cylinders, actuating direct from the cross-head four pumps with plungers 8½ in. diam. The stroke, designed for 10 ft., was variable under the control of the Davey valve-motion. These pumps forced the water into a large surface air-chamber, and from there down the shaft to the underground hydraulic pumps. The cylinders of this engine were 30 and 70 in. diam., respectively. An air-pump and cooling pond were used for condensing purposes. In each of the underground stations, cut at the 2400, 2600, and 3000-ft. levels, as the shaft was sunk there were placed two hydraulic engines. Each engine had four power-plungers of proper size to operate two pump-plungers that raised the water from the station to the Sutro Tunnel discharge. The ratio of the power-plungers to the pump-plungers was properly proportioned so that for a 10-ft. stroke the pumps could make about six or seven strokes per minute. After a trial of a few months, with numerous breaks and want of satisfactory results as to efficiency, the use of the surface-power engine was abandoned. A 12-in. pipe was laid from the Virginia & Gold Hill Water Co.'s tank near their flume, which gave a pressure-head of 2016 ft. to the Sutro level. With this steady power the pumps worked smoothly, without a jar, and gave quite efficient results. Under this system of pumping, all the water used for pumping was discharged with the mine-water through the Sutro drain.

At the Yellow Jacket, Belcher, Overman, Alta, Ophir, C. & C. shafts, and at several other points, large Cornish pumps were installed and gave fairly efficient service until their capacity was greatly over-taxed. All of the above-mentioned pumping machinery cost, without foundations, installation, or freight, about \$1,300,000. Its maximum pumping capacity, all told, was less than 5400 gal. per minute, lifting an average height of 1152 ft. The cost for six months, taken from the books of the different companies, for operating the same was \$34.13 for each indicated horse-power per month. The average water pumped

during that time was 5040 gal. per minute, raised an average distance of 1074 ft. The total indicated horse-power was 1703. The cost per month was \$58,120, or \$697,440 per year. This does not include the cost of new fly-wheels, broken bobs, strapping-plates, pump-rods, or new plungers, but represents the daily operating expense for pumping.

As for the enormous cost of operating expenses, it must be borne in mind that a great part was due to the local conditions, not to be found in any other mines the world over, hot water often reaching 160° F., at an elevation of 6000 ft. above the level of the sea. Ice was one of the staples in the list of supplies and lubricants for plungers, and all under-

ciency is only about 25% at best, but the cost of repairs is very small and the reliability superior to other systems. At a depth of 450 ft. below the Sutro Tunnel level the limit of power from the water-supply was reached, and on the 2150-ft. level a large electrical pumping-plant, with a capacity of 4500 gal. per minute, was installed. This plant consists of three duplex, double-acting ($6\frac{11}{16}$ by 24-in.) pumps, driven by three 225-hp. Westinghouse type C motors. The pumps are of the ordinary Riedler pattern, with mechanically closed valves, and operate at 110 rev. per min. Compared with the previously mentioned pumping plants, this shows a marked advance in engineering methods; and the cost, which is about \$80,000 in

Pumping Engine, Mexican-Union Shaft.

ground bearings were rapidly consumed, and otherwise wasted. The wood burned cost \$10 per cord, and in the previous year cost \$12. From January 1882 up to January 1884, the C. & C. Shaft Co. paid \$6000 per month for water-power to operate their hydraulic pumps, and \$10,000 after that date. This water was furnished under a static head of 2016.5 ft. to the Sutro Tunnel level. As an average of six months pumping in 1884, from the 2400 and 2600-ft. levels with the hydraulic pump, the cost of water raised per horse-power was \$20 per month, a little more than the cost of wood with the Cornish system. But in 1886, when the 3000-ft. level pump was running, the price fell to \$11.50 per pump horse-power.

In comparison with the above enormous pumping equipment, high costs and operating expense, a brief description of the present electrical pumping equipment at the C. & C. shaft may be interesting. Hydraulic elevators were installed in the C. & C. shaft, and with them, in connection with the electric pumps, the water has been lowered 750 ft. Under existing conditions, I believe this device is the most practical sinking pump in existence. It is true that the effi-

Pumping Engine, Forman Shaft.

running order, is but a fraction of what was formerly paid, while the running expense is about \$4000 per month.

YUKON TERRITORY WEST OF LEWIS RIVER.

By D. D. CAIRNES.

*The season of 1908 was chiefly devoted to the mapping and geological examination of those areas north of Whitehorse and south of Tantalus known to contain coal or to be underlain by coal-bearing formations, it being more particularly desired to ascertain the nearest points accessible to Whitehorse at which coking coal similar to that at Tantalus could be obtained. The entire district strictly belongs to the interior plateau region of the Yukon Territory, which, originally eroded to peneplain conditions, was subsequently subjected to a rather rapid uplift.

There are two coal-bearing horizons of economic interest in this portion of the Yukon Territory. An upper horizon occurs near the top of the thick assem-

*Abstracted from Summary Report, Geological Survey Branch, Department of Mines, Canada, 1908.

blage of conglomerate beds forming the upper half of the group of Cretaceous sediments, and to this higher zone belong the seams at the Tantalus mine and on Tantalus bluff. A second, lower coal-bearing horizon lies toward the base of the Cretaceous column as seen at the Five Fingers mine, also at a point west of the 69-mile post from Whitehorse on the Whitehorse-Dawson road, and elsewhere. The seams of the Tantalus bluff and the Tantalus mine doubtless extend a number of miles to the north and south of these places, but prospecting for coal is rendered particularly difficult there by the thick mantle of glacial and recent alluvial material which covers the greater part of the district. Beginning within a distance of two or three miles south of Tantalus, the Cretaceous sedimentary rocks are, for the greater part, covered with more recent Tertiary basalts, basalt tuffs, etc., so that careful prospecting will be necessary to find it suitably located for mining purposes.

About four miles west of mile-post 69 from Whitehorse a number of seams have been uncovered, and probably others exist. Of the seams seen, one was 7 ft., another 4 ft., and several between 6 and 8 in. thick. Samples analyzed by F. G. Wait gave the following results:

| | I. | II. | III. |
|---------------------------|-------|-------|-------|
| Water | 8.98 | 12.02 | 4.68 |
| Volatile combustible | 29.62 | 34.28 | 15.59 |

| Ash | 13.10 | 11.14 | 7.47 |

Sample I represented the average of an 18-in. bed, II of a 7½-ft. bed, and III of a 2-ft. bed, seen between mile-posts 113 and 114.

A few miles southwest of Montague are a number of claims, locally known as 'Macks copper'. The property is reached by a branch road leaving the Whitehorse-Dawson road, about six miles above Montague and following approximately the old Dalton trail southwesterly up the Hutchi river. From a point about eight miles in on this road a trail ascends the hills to the north of the claims, which virtually are on the summits, about four miles distant from and 1900 ft. above the valley. Practically all the ore in the vicinity appears to be on one claim. It appears in a fine-grained greenish porphyrite, at or near its contact with limestone, and consists chiefly of magnetite, with hematite in minor quantities, both being more or less impregnated with copper minerals, chiefly chalcopyrite, malachite, and azurite. The main mass of mineral is in the form of a small knoll of iron ore, about 200 ft. wide by perhaps 300 or 400 ft. long. On the south side of the hill the iron carries considerable copper, while the ore on the top shows none. The orebody in the more westerly locality is only 10 to 12 ft. wide, and lies next to and more or less in the limestone. The following samples were taken by the writer and have been assayed by Robert Smart, Government assayer at Whitehorse. No. I is an average from the end of a tunnel, No. II is an average of the best 4 ft. of the open-cut:

| | I. | II. |
|------------------------------|-------|-------|
| Gold, ounces per ton..... | Trace | 0.025 |
| Silver, ounces per ton | Trace | 3.400 |
| Copper, percentage | 1.80 | 5.55 |

On both sides of Gilltana lake, which lies some 15

miles in a northwesterly direction from Hutchi lake and village, are claims known both as the Gilltana Lake claims and as the Hutchi copper. The ore on the northwest side of the lake occurs at the contact between granite and limestone, and is in the form of narrow lenses of mineralized matter and quartz. The widest lens seen had a breadth of about 4 ft., but as a rule the bodies are only from 1 to 2 ft. wide and have at present no economic value. Across the lake the claims are chiefly located over the face of a hill rising about 1200 ft. above the water. The country rock consists mainly of mica schists, interbanded with which are some beds of quartzite and limestone, the latter generally being narrow—3 to 4 ft. wide, but sometimes as much as 50 ft. thick. The strata strike about parallel with the lake and dip into the hill, so that the different bands of schist extend along the face of the hill, one above the other, maintaining an almost horizontal outcrop. In places these bands have become mineralized with magnetite, generally carrying copper minerals, chiefly chalcopyrite and malachite, and these constitute the orebodies. The original schists show all degrees of mineralization and replacement, from portions entirely non-metalliferous to others now consisting of almost solid iron ore.

The best of these mineralized bands or zones average from 6 to 10 ft. in width, although one was seen having a breadth of 20 ft. and consisting of almost solid ore. The mineralized bands generally can be traced for 50 to 100, or even 200 ft., when the iron and copper minerals gradually disappear, or at times seem to be continued along other parallel bands. Three prominent, with other less important bands, were observed at different elevations on the face of the hill. At the surface the copper minerals appear to have been leached out. On the Helen claim, up Franklin creek, some open-cut work has been done, and there in places streaks of copper ore 1 to 3 ft. thick were seen, included in wider bands that are much richer than observed elsewhere.

Apparently the ores are connected in origin with the intrusive granites found in the vicinity. The strata have been cut by dikes of light colored hornblende andesites and dark fine-grained basalts, but these have had no visible effects on the ore deposits. The district is well worth prospecting and a number of the claims look very promising. The following represent the results of assays of two samples from this district. No. I is a sample taken across the strike of one of the best looking bands, which had a width of about 6 ft. No. II is a sample of one of the 3-ft. streaks of copper ore on the Helen claim.

Since the season of 1905 the Venus, on Windy Arm, has been worked continuously, with very satisfactory results, so that now a large amount of ore has been blocked out and some small high-grade shipments have been made to outside points. During the past year this is the only property in the district upon which important work has been performed.

STATE GEOLOGICAL SURVEYS.

Officers of the various geological surveys are now planning for a busy season. Below we give outlines of the work to be undertaken in several States.

Alabama. Work in this State is at present largely concentrated on studies of the Coastal Plain. Plans for the season include conference trips of E. A. Smith, State Geologist, with E. H. Sellards, of Florida, and T. W. Vaughan, of the U. S. Geological Survey, along various rivers, continuing the work of last season. During the summer the offices of the Survey will be moved into Smith Hall, the beautiful museum building designed to shelter the geological collections, and now nearing completion.

Arkansas. A. H. Purdue, State Geologist, will spend most of the season working on the geology of the Ouachita mountains. A party under W. N. Gladson will measure the available water-power of White river and its tributaries. A. A. Steel will study the coal mines with a view to developing methods of conserving the coal. H. D. Miser will take up the study of the clays. Samples will be collected and physical tests made at the U. S. Geological Survey testing plant at Pittsburg. This work will be supplementary to the report on Arkansas clays prepared by J. C. Branner and recently issued.*

Colorado. The Colorado legislature was generous this year; so generous that about a million and a quarter was appropriated above the revenues of the State. The Governor, in vetoing individual items, cut out the \$10,000 appropriated for co-operative topographic surveys, and part of the sum set aside for the regular geological work. As a net result, R. D. George, State Geologist, has only \$10,000 available for this season. The plans include the survey of the Monarch-Garfield district of Chaffee county, a study of the placer deposits near La Veta pass in Costilla county, and a continuation of the investigation of the clays of the State. About the middle of the summer a party sent either into the San Juan southeast of Silverton, or near Granite, south of Leadville. The physical and chemical testing of the building stones will be continued, and a bibliography of the geology of the State is expected to be ready for the printer before Christmas.

Florida. E. H. Sellards, State Geologist, expects to publish this season a progress report on fullers earth. A report on the general geology and stratigraphy of the State prepared by the U. S. Geological Survey in co-operation with the Florida Survey also awaits publication. It is expected that a preliminary report on the peat deposits of Florida will be published during the present year. Investigations preparatory to a report on the phosphate deposits are in progress.

Georgia. S. W. McCallie, State Geologist, with his assistants, will devote the present field season principally to a study of the limestone and cement materials of the State. The asbestos deposits will also be investigated.

Illinois. Preliminary plans only are as yet available, since the General Assembly has but recently ad-

journed. The work will be under the charge of Frank W. DeWolf, Acting Director, and will include topographical and geological surveys throughout the State. In the lead and zinc area near Galena large scale detailed maps will be made by G. H. Cox. E. W. Shaw, of the U. S. Geological Survey, has been detailed to take up the co-operative studies of the coalfields. E. F. Lines will continue his work on the clays. David White and E. F. Burchard will study the stratigraphy of the coal measures and the character of the available road materials, respectively. R. S. Blatchley will survey the oilfields, and J. A. Udden, Stuart Weller, Jon Udden, and other members of the corps will continue their work of last year. A slight increase of funds is available.

Indiana. W. S. Blatchley, State Geologist, will devote personal attention to the oilfield near Oakland City. This promises to become one of some importance. C. W. Shannon and A. E. Taylor will continue soil surveys in the southern part of the State. W. M. Tucker is measuring the water powers. A revised edition of G. H. Ashley's report on the coalfields, based on re-surveys made by himself and E. F. Lines last season, is in press.

Maryland. W. B. Clark, State Geologist, reports that this season the Maryland Geological Survey will complete special reports on the lime and cement industries and on the iron ores. The work on the Devonian will also be finished, while that on the Lower Cretaceous will be continued. Areal surveys in Anne Arundel and Talbot counties will be undertaken, and in co-operation with the U. S. Geological Survey a special survey will be made of the water resources. The Highway Division of the Survey has under construction \$350,000 worth of roads, and applications have been filed for roads to the amount of \$250,000 additional.

Michigan. A. C. Lane, State Geologist, has resigned to accept a position in Tufts College. His successor has not yet been announced. Mr. Lane will remain temporarily at Houghton, continuing his studies of the grain of rocks and of mine waters.

Mississippi. A. F. Crider has resigned to accept a position with a marble company in Alabama. E. N. Lowe has been appointed State Geologist to succeed him.

Missouri. The appropriation for the next biennial period has been fixed at \$35,000, a substantial increase. H. A. Buehler, State Geologist, expects, in co-operation with the U. S. Geological Survey, to take up a systematic re-study of the coalfields, and also to make surveys of the Aurora, Wentworth, Stotts City, and Sarcoux areas, in the southwestern lead and zinc region. Mapping will be carried on near Ste. Genevieve and Rolla, and a special re-study of the iron ores of the State is planned.

New Jersey. H. B. Kummel, State Geologist, reports that the principal new work for the year will be the inauguration of soil surveys in co-operation with the State Agricultural Experiment Station and the Bureau of Soils at Washington. In connection with the Road Department all the asphaltum binder used on the State macadam roads will be tested. Folios discussing the geology of various important areas will be issued.

*Bull. 351, U. S. Geol. Survey.

New York. John M. Clarke, State Geologist, has under way a variety of interesting researches. The depleted condition of the Saratoga mineral waters, the heated litigation over them during the past few years, recent drastic legislation designed to suppress the production of natural carbon dioxide derived from them, and the new statute which has bonded the State for the purpose of taking over as a public preserve as much of the mineral spring property as seems wise in the judgment of the newly appointed commission, have made it imperative to acquire more accurate information in regard to the tectonic conditions in Saratoga county and the relations between them, the salines, and the carbon dioxide pressure. Special attention will be given this year to the problems presented by these springs. The study of the crystalline rocks is in charge of H. P. Cushing and W. J. Miller, the Paleozoics will be studied by R. Ruedemann, the special tectonic and economic problems by D. H. Newland, and the crystallographic analysis of the mineral waters will be in charge of H. P. Whitlock. In the eastern Adirondacks J. F. Kemp will continue his work on the crystalline geology of the quadrangles in Essex and Clinton counties, and in southeastern New York Charles P. Berkey will carry on the study of the complicated crystalline rocks from the Highlands southward to Manhattan, in co-operation with the New York City Board of Water Supply. This work will be supplemented by the survey of Westchester county to be made by C. E. Gordon. In western New York additional areal work in the higher Paleozoics will be continued by D. D. Luther. The gypsum industry, which has reached very large proportions in this State, will be investigated by Henry Leighton.

North Dakota. The small appropriation available in this State limits the work severely. A. G. Leonard, State Geologist, will, however, in co-operation with the U. S. Geological Survey, study the geology of the Bismarck quadrangle while an assistant is at work in the central part of the State on the coal-beds and underground waters. The Fifth Biennial Report is now in press. It includes reports on the coal deposits of the southwestern, and cement materials of the northeastern, part of the State.

Oklahoma. C. N. Gould, Director, reports that during the present summer it is planned to have several parties in the field. D. W. Ohern, in the north-central part of the State will investigate the occurrence of oil and gas, portland cement rock, and shales. He will be assisted by Frank A. Herald, Key Wolf, Warren Hazeltine, and A. C. Reeds. L. L. Hutchison, Assistant Director, will study the asphalt deposits in the southern part of the State. He will be assisted by B. C. Belt. Mr. Hutchison's preliminary report on the oil and gas deposits is about completed and, with the asphalt report, will be published some time during the summer. Mr. Gould is himself at work on a report on the building material of Oklahoma and hopes within a year to have published reports on the clays and shales. L. C. Snider, recently appointed chemist, will spend the summer in the U. S. Geological Survey testing plant at Pittsburg, making tests of several hundred samples of Oklahoma clays.

Pennsylvania. There is no State Geologist of Pennsylvania at present, though the Geologic and Topographic Survey Commission, of which R. H. Hice is secretary, has in contemplation the organization of a State corps. So far the work has been done in co-operation with the U. S. Geological Survey. It is probable, in view of reduced appropriations, that little field work will be undertaken this year, attention being concentrated instead on publication of accumulated materials.

Washington. The Geological Survey which was discontinued in 1903 has been revived and Henry Landes has been re-appointed State Geologist. He will be assisted by S. Shedd, of Pullman.

CANADIAN GEOLOGICAL SURVEY.

The field assignments for 1909 are given in the *Canadian Mining Journal* as follows:

D. D. Cairnes will have a party in the Wheaton-Watson Rivers region, in southwestern Yukon. R. G. McConnell will complete his examination of the geology and mineral resources of Ténada island. F. H. McLaren will finish his topographic map of Ténada island. W. W. Leach is engaged in mapping in the vicinity of Hazelton, Skeena river, and will examine in detail the coal area near Telkwa, discovered by him last season. C. H. Clapp will continue his geological investigations on Vancouver island. R. H. Chapman will begin a topographical survey of Vancouver island. W. Sutton will report on the coal beds of the east coast of Vancouver island. Charles Camsell will continue work in the Similkameen district, more particularly in the Tulameen River district. L. Reinecke will complete the topographical map of the Tulameen and begin a survey of the west fork of the Kettle river. George Malloch will make a geological survey of the Fort George region on the Grand Trunk Pacific. O. E. LeRoy will study the geology and ore deposits of the Slocan. He is now completing a geological map of the Sheep Creek mining camp. W. H. Boyd will make a topographical map of the Slocan. S. J. Schofield will be employed in mapping in the East Kootenay district. John Macoun is continuing his natural history collecting in the West. D. B. Dowling will investigate the coal lands of Alberta west of Edmonton. W. McInnes will continue his geological investigations in the district north of Edmonton. W. H. Collins is continuing his examination of the Gowganda district. W. A. Johnston will resume his mapping of the Lake Simcoe region. M. E. Wilson will be working north of Lake Temiskaming. G. A. Young will continue his work in the Bathurst district, New Brunswick. J. A. Dresser will continue his investigations on the rocks and economic minerals of the Eastern Townships. R. W. Ells will complete his investigations of the oil shales of New Brunswick, and examine the shales of Nova Scotia and Gaspe. E. R. Faribault will continue mapping the gold-bearing rocks of Nova Scotia. H. Fletcher's field season will be spent studying the coal formations of Cumberland county. Heinrich Ries, accompanied by Joseph Keele, will begin a study of the clays of the Dominion. The Maritime Provinces will be examined this season.

GOLD AND SCHEELITE NEAR MACRAES, NEW ZEALAND.

Written for the MINING AND SCIENTIFIC PRESS
By PERCY MORGAN.

The association of scheelite, tungstate of lime, with auriferous quartz veins traversing schistose rocks may be observed in many localities in the South Island of New Zealand. One of these is in the old district of Marlborough, in the northeast of the South Island. The other localities are nearly all in the southern Province of Otago, the best known being Saddle Hill, near Dunedin, Macraes, Mt. Highlay, Bendigo, near Cromwell, and Glenorchy, at the head of Lake Wakatipu. At all these places the quartz veins have been more or less worked for gold or

scheelite or both. Up to the present time the most notable development of gold-scheelite veins has been near Macraes. A few observations made by the writer during a recent visit to this district may be of some interest. Macraes is a small settlement situated about 40 miles north of Dunedin, the principal town of Otago, from which it may be reached in a few hours by rail and coach. Near the township may be seen the abandoned workings on the Duke of Edinburgh reef. This lode is said to have yielded payable ore for some time, and with modern and economical methods of working could probably be profitably re-worked. Like the other veins of the district, it runs with the bedding planes of the mica-schists, which are here also the planes of schistosity. Since the schists in this part of Otago are as a rule very slightly folded, it follows that the quartz veins lie unusually flat. They seem to be confined to a certain horizon of the schists two or three hundred feet

in thickness, and so far as my observations go are confined to the anticlinal portions of the folds. They may therefore be regarded as extreme types of saddle reefs.

The principal mine of the district is the Golden Point mine, owned by Messrs. W. and G. Donaldson, and situated a few miles west of Macraes, in the valley of Deepdell creek, the lode now being operated on crops out on the eastern side of the valley, about 200 ft. above the mill. It averages $2\frac{1}{2}$ to 3 ft. in thickness, strikes N. N. W., and has for the most part a very gentle dip to the E. N. E. In places it is almost or quite flat. The lode matter is generally a mixture of small irregular veins and masses of quartz with mica-schist and material of nondescript type. Some parts of the lode consist of solid quartz, while others show little or no quartz. As a rule the walls, or in this case one might say the roof and the floor, are not very sharply defined. The ore generally contains from 5 dwt. to 1 oz. of gold per ton, while the scheelite ordinarily ranges from $1\frac{1}{2}$ to 2 or 3%. Near the outcrop the ore contains a good deal of iron oxide, but at a little distance from daylight pyrite and arsenopyrite begin to take its place. The gold is usually fine and is distributed through the quartz and other vein matter. It is alloyed with a little silver. The bulk, if not all, of the scheelite occurs in a quartz matrix, and has evidently been deposited contemporaneously with the latter mineral. The quartz often carries a high percentage of tungstate of lime, and sometimes the scheelite predominates to such an extent that the ore can be hand-picked. Such quartz, however, is often low in gold content.

Owing to the flatness of the lode, the ore is extracted from the mine by a somewhat irregular system of drifts and cross-cuts. Where the lode is thin or poor, pillars are left. Timber, an expensive item in a district naturally destitute of trees, is used where necessary. From the mine the ore is conveyed by an inclined tramway to the mill below. The ore-crushing appliances consist of a rock-breaker and 10 stamps, each weighing about 1000 lb. The stamps are given 100 drops of 7 in. per minute. The motive power is water, supplemented by steam. From the stamps the crushed ore passes over amalgamated copper plates, and is then conveyed to a V-shaped separating box. The fine material contained in the overflow from the box is concentrated on a Frue vanner, while the coarser material goes to a Woodbury concentrator. The concentrate, which contains about 30% of scheelite, is dried, bagged, and shipped to Germany. Experiments are being made to eliminate the iron and arsenical pyrite by roasting the concentrate, and then re-treating. A much higher grade of shipping material is thus expected to be obtained. I did not learn what amount of gold there is in the concentrate, but probably it is considerable. The tailing from the vanners is now being successfully treated in a small cyanide plant lately erected. Formerly, though some was saved in pits, it was for the most part run to waste. At Mt. Highlay, a few miles west of the Golden Point mine, a flat-lying bedded lode 10 or 12 ft. thick and of considerable horizontal extent was formerly worked on a small scale by

various owners. Messrs. W. and G. Donaldson now hold under Government lease practically all the old claims. Ore is being won chiefly from an open-cut near the top of a hill. The dip of the lode is here seen to increase gradually with depth, and in a low level drift the lode is vertical or even slightly overturned. This feature appears to be due to faulting. Much of the ore being mined is of low grade both in gold and silver, but it can be cheaply extracted and treated. It is conveyed by a self-acting inclined tram to the mill near the foot of the hill. The crushing plant here consists of a rock-breaker, 5 stamps (not set up at the time of my visit), and a 5-ft. Huntington mill. This latter machine does good work on the soft ore. It is run at 65 revolutions per minute, and crushes 30 to 35 tons of ore per 24 hours. The crushed material is run over copper plates, and then without sizing passed over a Wilfley concentrator. At the time of my visit the tailing was considered too poor to save, but a cyanide plant was being erected to treat the tailing from the richer ore, which it was proposed to mine and treat in the near future.

As regards the genesis of the ore in the quartz-scheelite veins of Macraes and other New Zealand localities, the chief point of interest is concerned with the origin of the scheelite. A. M. Finlayson* has suggested that the scheelite was formed by the combination of tungstic acid derived from granitic magma underlying the schists, with lime derived from the country enclosing the lodes. Though several objections may be urged against this theory, it is probably the best working hypothesis that can be advanced at the present time.

Low-grade porphyry copper deposits now developed in the United States represent 185,000,000 tons of ore, which will average about 1.7% net recoverable copper. Below is a list of all the low-grade milling properties, with capitalization, ore reserves, prospective output, and so forth:

| Company. | Number of shares. | Market value. | Present rate | |
|-----------------|-------------------|---------------|-----------------------|-------------|
| | | | Ore-tonnage estimate. | lb. copper. |
| Boston Con.... | 775,000 | \$ 12,000,000 | 37,000,000 | 20,000,000 |
| Utah Copper.. | 735,000 | 38,000,000 | 65,000,000 | 60,000,000 |
| Ohio Copper .. | 1,300,000 | 8,000,000 | 14,000,000 | (In prep.) |
| Nevada Con. . | 1,600,000 | 36,000,000 | 30,000,000 | 30,000,000 |
| Cumb.-Ely ... | 1,300,000 | 10,500,000 | 4,000,000 | 18,000,000 |
| Giroux | 1,300,000 | 10,500,000 | | |
| Miami | 600,000 | 9,000,000 | 13,000,000 | (In prep.) |
| Inspiration ... | 1,000,000 | 8,000,000 | | (In prep.) |
| Ray Central .. | 800,000 | 2,800,000 | 6,000,000 | |
| Ray Con. | 800,000 | 12,000,000 | 16,000,000 | (In prep.) |
| Total, | 10,210,000 | \$146,800,000 | 185,000,000 | 128,000,000 |

Stokers of furnaces must be set so that combustion will be complete before the gases strike the heating surface of the boiler. When partly burned gases at a temperature of, say, 2500° F., strike the tubes of a boiler at, say, 350° F., combustion is necessarily hindered and may be entirely arrested. The length of time required for the gases to pass from the coal to the heating-surface probably averages considerably less than one second, a fact which shows that the gases and air must be intimately mixed when large volumes of gas are distilled, as at times of hand-firing, or the gas must be distilled uniformly, as in a mechanical stoker.

*Transactions of the N. Z. Institute, Vol. XLII, 1908.

ACCOUNT NUMBERS.

Written for the MINING AND SCIENTIFIC PRESS.
By H. E. WEST.

No argument is necessary for the importance of accurate and itemized costs in all departments of mining. They are as necessary to small as to large undertakings. 'Loose-leaf forms filed in standard 'binders' permit such figures to be easily kept. Daily labor-tickets and labor-sheets are available, which are returned from the several departments and entered by the cost-clerk on the day-line of the monthly labor statement, and being finally totaled, show the cost of labor segregated for each department. Accurate costs are impossible unless such labor statements—and the same applies to store tickets—are used. If a written description of the work chargeable is attempted, much depends on the accuracy of description, and considerable confusion results. This the luckless cost-clerk must unravel as best he may. What are wanted are concise exact specifications of charges for both labor and material. Such a requirement is admirably filled by the use of numbers.

The method of using account numbers is already employed in all branches of business, factories, and mines, and has proved its utility. It is well adapted to smaller undertakings, where usually, for want of definite systems, the greatest inaccuracy regarding costs exists. The scheme is illustrated below from the accounts of a working mine:

WORK NUMBERS.

| | | |
|------------------------|-------------------------|-----|
| MINE DEPARTMENT. | SMITHS' SHOP | 302 |
| BREAKING ORE | Supplies | 303 |
| Explosives | ELECTRIC LIGHTING .. | 304 |

| FRAMING AND CARPEN- | STABLES | 413 |
| TER SHOP | Supplies | 414 |
| Supplies | GENERAL STORES | 415 |
| | Supplies | 416 |
| | LIGHTING, HEATING... | 417 |

Each department is given a series of numbers, as follows: The Mining Department takes numbers starting from 100; the Milling Department, numbers starting from 200; the Mechanical Department, from 300; the General Costs, from 400. Construction numbers start at 500. Doubtless alterations and improvements will readily suggest themselves for particular cases. The feature recommended, however, is the use of numbers for the charging of all labor and material. No description is permitted of any work done. It must fit into one of the several numbers. If the timekeeper or operator cannot be exact, how much less can the cost-clerk? Should an order come to the store without a number, it is returned for amendment. The same rule applies to all requisitions on the factory or other manufacturing departments. Some uncertainty may exist at first, but the employees will soon find that the actual number of figures employed is small. Copies of the scheme should be posted in conspicuous places, and such copies should be amended from time to time, especially with regard to construction numbers. When a construction account is closed it should be cancelled. On any new construction work being undertaken, the first thing to do is to have the number posted. Small orders passing through the shops, for outside work, etc., can be issued through 'Job Orders'; a card bearing a number, starting from 1000 for distinction, is issued, and when the work is completed the card is returned to the office, signed by the foreman, and with labor and material indicated. This affords concise specific information. The numbers are subject to abuse, it is true, but the mistake is usually self-evident and can be amended. In foreign countries where there are difficulties of language, especially in writing, the numbers will afford a ready means for the suitable description of any particular work.

HYDRAULIC DREDGING FOR GOLD.

By HENRY G. GRANGER.

*Repeated failures in attempts to work gold-bearing gravels by means of suction-dredges have created the impression that this method is impracticable. The suction-dredges have failed from three special causes: excessive wear and frequent breakage of pump-shell, runners, and liners; inability to dredge compact gravel which would not readily move toward the intake; and, most important of all, closing of the suction-pipe by stones too large to enter it. In my opinion, all three causes of trouble may be remedied: the first, by making stronger the parts most liable to wear and breakage; the second, by means for loosening the gravel at the intake; and the third, by sufficiently increasing the diameter of the suction-pipe. In suction gold-dredges, this diameter has not usually exceeded 10 or 12 in.; whereas there are few profitable goldfields which can be considered dredgeable, in which stones more than 12 in. diam. are not frequently encountered. In harbor-operations, much larger stones are handled by suction-dredges. The large dredge of the Henry Steers Contracting Co. worked for nearly four years at

League Island, Philadelphia, where it sucked up, passed through the pump, and forced through 3700 ft. of discharge-pipe, gravel containing boulders up to 200 lb. in weight. This was done with no bad breaks and few shut-downs. The cutter and liners were the only parts liable to damage, and these were easily replaced with brief interruption of work. The chrome-steel liners are said to have lasted six to nine months. I am informed that this dredge worked continuously for nine months at Harrison, New Jersey, on gravel, much of which carried stones as large as a man's head.

The essential features of this dredge are as follows:

The centrifugal pump, made by the Morris Machine Co., of Baldwinsville, New York, was designed for a 22-in. suction, discharges at the bottom, and is driven at 225 rev. per min. Its shell is approximately 84 in. diam., with a runner about 60 in. diam. The runner-bearing has a water-sleeve to keep the sand out, supplied by a small force-pump worked at 60-lb. pressure. The pump is set 30 ft. from the bow. Power is supplied by a compound marine engine, with surface-condenser, 22 by 42 by 26-in stroke, running 90 rev. per min. On the engine shaft is a 65-in. gear with wooden cogs, driving a 26-in. steel pinion. The wooden cogs are said to run about six months before renewal. On the pump-shaft keyed into the pinion is a slipping spring coupling. When a stone or log, too large to go through, gets into the shell, the runner is brought to a full stop without damage. This occasionally happens, and the obstacle may be removed by taking off the plate, with a loss of time averaging not more than 15 minutes. The pump uses from 450 to 500 hp., which is considerably in excess of the economical requirement of a pump of this size, but with it the material may be forced through a pipe-line 4000 ft. long. I am told that, with 1000 ft. of discharge-pipe, 1000 cu. yd. of gravel per hour may easily be handled. The total power used on the dredge is 800 horse-power.

The winch, with its various barrels for working-lines, suction and cutter-hoisting lines, and spud-hoisting lines, is a Lidgerwood machine, with two cylinders 14 by 18 in. The winch-engine also drives a chrome-steel gear, which through a shaft drives a 7-ft. chrome-steel cutter. The cutter-shaft is connected with and driven by a universal joint. The wrought-iron suction-pipe, the mouth of which is just above the lower rim, of the cutter, is connected by a flexible rubber joint to the cast-iron pipe which extends to the pump. The two timbers used as braces for the shaft and pipe are so hinged that their movement can only be vertical. The wrought-iron suction-pipe lasts for a year; the cast-iron pipe, including the elbow running from the rubber joint to the pump, lasts four years.

This is said to be the largest suction-dredge in the world that has continuously handled coarse gravel, and in capacity is the largest gravel-dredge of any class. The outboard suction is 54 ft. long, and the dredge can work to a depth of 30 ft. I am told that it has frequently sucked up from the bottom heavy spikes and tools which had been dropped into the water several feet in advance of the pipe.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING LEASE—ACCEPTANCE.

A coal lease executed by the life tenant and part of the remainder-men only, and not signed by the lessee, was not accepted and adopted by the parties so as to make it binding where the lessee corporation, by its agents, simply went on the premises to investigate and discovered coal in workable quantities, the lessee never having advised the lessors to that effect nor decided what to do, where it had the option to determine whether it would mine the coal. Neither the life tenant nor remainder-men could have enforced the lease, nor could the lessee have done so without signing and electing to proceed to mine coal thereunder.

Greenridge Fuel Co. v. Littlejohn, (Iowa) 119 North-west. 698, Feb. '09.

ACTION AGAINST MINE OWNER FOR INJURIES—PLEADING.

In an action against a mine-owner for injuries to real property, due to mining operations below the surface, the complaint must state facts showing whether the mine-owner was a trespasser, or whether he acted under any right in making the excavation, and it must also allege the time when the injury occurred, as under the statute, the action must be brought within one year from the time of the injuries.

Sloss-Sheffield Steel & Iron Co. v. Sampson, (Ala.) 48 South. 493, Jan. '09.

LEASE TO MINE—LIABILITY OF LESSEE FOR ROYALTY.

The lease of a coal mine stipulated that the lessee should mine not less than 8000 tons per year, and he was to pay a royalty on that amount, whether mined or not, at 5c. per ton, unless he was unavoidably prevented from taking out the coal, but he was to be liable for the royalty. In an action for the royalty it was decided that the lessee was not liable where the mine could not be operated; and evidence was proper as to whether the mine could be operated at a profit, and the lessee was justified in abandoning the mine.

Wilson v. Big Joe Bluff Coal Co., (Iowa) 119 North-west. 604, Feb. '09.

MINING—COMPETENCY OF EXPERT.

Men of experience in mine-working who are capable of determining the quality of coal taken from a particular mine, who can state whether coal was properly mined, and the cost approximately of mining it, and who knew the market price of coal, were competent to express an opinion as to whether the particular mine could be operated at a profit.

Wilson v. Big Joe Bluff Coal Co., (Iowa) 119 North-west. 604, Feb. '09.

CONSTRUCTION OF OIL LEASE.

An oil lease which granted to the lessee the exclusive right to mine for and produce oil and natural gas from a certain tract of land, and which granted the possession of so much of such land as might be necessary therefor, did not give the lessee the right to use any portion of the land for cultivation, or for residences and conveniences for employees, but confined the occupancy and use of the surface to so much of such land as was strictly necessary for mining and producing purposes.

Fowler v. Delaplain, (Ohio) 87 Northeast. 260, Jan. '09.

MASTER AND SERVANT—DUTY TO LIGHT MINES.

A coal miner approaching the bottom of the shaft from above, with a view of leaving the cage, or approaching the bottom of the shaft from his working place below, with a view of entering the cage, is within the protection of the Illinois statute which provides that so long as there are miners underground, the operator shall maintain sufficient light at the bottom of the shaft so that persons coming to the bottom may discern the cage and objects in the vicinity.

Robertson v. Donk Brothers Coal & Coke Co., (Ill.) 87 Northeast. 373, Feb. '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

BIENNIAL REPORT OF THE STATE GEOLOGIST (Missouri). By H. A. Buehler. pp. 59. Jefferson City, 1909.

VALUATION OF UNCONFORMITIES. By Eliot Blackwelder. Jour. Geol., Vol. 17, pp. 289-299. Chicago, 1909.

SMOKELESS COMBUSTION OF COAL IN BOILER PLANTS. By D. T. Randall and H. W. Weeks. U. S. Geol. Survey. pp. 186. Washington, 1909.

PRODUCTION OF PHOSPHATE ROCK IN 1908. By F. B. Van Horn. U. S. Geol. Survey. Mineral Resources of the United States for 1908. pp. 16. Washington, 1909.

Commercial Paragraphs.

The JOHN A. ROEBLING'S SONS Co. is soon to issue a booklet illustrating the proper way to attach sockets to wire rope. It will be ready about August 1.

The UNION IRON WORKS, San Francisco, last week sold to the Tonopah Extension Mining Co., of Tonopah, Nevada, a 30-stamp 'Union' battery complete.

THE FOOS GAS ENGINE Co., Springfield, Ohio, reports that its business during May 1909 was considerably larger than for the same month of any previous year. The month of April showed the largest business ever done in a single month, and the first five months of the present year show a greater business than has ever been done in the same period. As an indication of returning prosperity these facts are gratifying, and of prospects for the future it is welcome to note that the Foos Gas Engine Co. is increasing its facilities and that the plant is running at its fullest capacity 19 hours per day.

The DENVER QUARTZ MILL & CRUSHER Co., Denver, Colorado, is placing on the market a quartz-mill for which it claims great efficiency and capacity. The machine is of the Chilean mill type, the grinding being done by rolls or mullers, traveling in circular mortar or ring die. The largest mill is 5 ft. 6 in. diam., with six rolls 23 in. diam. by 8 in. wide, each weighing 800 lb., revolving around a circle 15 ft. 6 in. diam., at a rate of 30 rev. per min. The discharge is through a screen completely enclosing the grinding mechanism of the mill. The feed is arranged to take the ore direct from the crusher. The drive is so arranged that no oil can get into the ore and hinder subsequent treatment. One particular advantage of the mill would appear to be the accessibility of its wearing parts and the ease with which renewals or necessary repairs may be made.

Catalogues Received.

The HENDRIE & BOLTHOFF MFG. & SUPPLY Co., of Denver, Colo., is distributing a pamphlet called 'Power Irrigation'. While primarily designed for those interested in irrigation, it is of general value because of the unusual amount of data about small pumping plants that it contains. "Don't forget that pumping with power is an engineering subject requiring broad knowledge of hydraulics, electricity, and power engineering in general. Don't forget that metal is required to make good machinery, and that weight cannot be cut below a certain amount without detriment. Don't forget that speed means power, and that you can get more power from a motor or engine operating at a high speed than from one of the same size and weight running at low speed." These are all bits of advice as valuable to miners as to farmers. The rules given for rough estimates of power required for various situations, and estimates of cost, will be valuable to all proposing to install small plants, while the directions for priming and running centrifugal pumps, if faithfully followed, will save much delay and trouble. The numerous tables and illustrations add to the value of the book.

EDITORIAL.

AN average of 72.5 pounds of copper per ton was the amount recovered from the ores mined at Butte during the month of June.

WEDDINGS are joyful occasions, and much to be encouraged. At least the Central India Railway Company believes so, since decrease in Hindu marriage celebrations has seriously cut revenues from passenger traffic. The silver miners are yet to be heard from.

CONSTRUCTION of the Cape to Cairo railroad goes steadily forward, and, as is usual with pioneer railroad enterprises, the building is from mine to mine. Contracts have recently been let to connect the Star of the Kongo mine, in the Kongo Free State, with Broken Hill, in Rhodesia.

PIG IRON production shows a significant and gratifying increase, according to figures furnished by the Bureau of Statistics. In May the amount produced, 1,880,098 tons, was nearly 60 per cent ahead of production for the same month of 1908. For the first five months of this year the output has shown an almost equal increase.

UTILIZATION of the continuous revolving filter for slimes is reported from South Africa, being applied in the Rand mills by Mr. W. A. Caldecott. This system, employing a permanent sand filter-bed, and a scraper to remove the slime after the vacuum has exhausted the cyanide solution, was introduced into American practice by Mr. Bertram Hunt only a year ago. It is pleasing to note this recognition of a meritorious innovation in cyanide work.

RUMORS of consolidations of copper properties are heard on all sides. The advantages of a union of the Utah Copper and Boston Consolidated are being debated at Salt Lake, while the British Columbia Copper and the Dominion Copper companies are also coquetting. Since the Lewisohn interests secured control of the British Columbia there is already some community of interest between these two Canadian companies. Both consolidations have much to commend them, and seem likely to be brought about now or later.

RHODESIA has a system of inspection which provides quite effectually for the enforcement of regulations regarding assessment work. In the United States we take the oath of an interested party. As a result, it is exceptional in many camps for a bona fide \$100 worth of work, as provided by law, to be annually done on each claim. In places the matter is a farce, and we are told of one Nevada camp in which no genuine assessment work has been done for five

years. The net result is to tie up considerable areas, withdrawing them from real prospecting, and to defeat the very object of the law. We fear that the poor prospectors as well as the wicked corporations are in some need of a moral uplift.

WISCONSIN evidently appreciates the work being done by its Geological and Natural History Survey, since to the regular annual appropriations of \$10,000 each for road studies, and for geological work a third \$10,000 has been added for soil surveys. Plans for the season are now being made. In Washington the Geological Survey has been re-established, with appropriations for the biennial period of \$25,000 for geology, \$10,000 for hydrographic studies, and \$20,000 for topographic surveys. Other States have made the usual appropriations, and this will be a busy season for the geologists.

ILLINOIS is to have a School of Mines connected with its University. It was asked for by a committee representing the miners, operators, inspectors, and manufacturers, and the General Assembly promptly voted the money. It is understood that the men will be especially trained to work in and investigate the problems of coal mining. This is quite as it should be. While we have many mining schools in the United States, but little attention has been paid to the peculiar features of coal mining. It is appropriate that Illinois should lead in this, and it is well that the schools should differentiate rather than duplicate.

ANNOUNCEMENT of acceptance by the Paris Bourse of United States Steel common proves to have been premature. Mr. J. Pierpont Morgan evidently enjoys greater favor at the Vatican than among the guardians of French conservatism in finance. Extensive dealing in American securities has been practised of late by Frenchmen, placing orders through Paris banking houses which have connections in New York. The managers of the Bourse fear a sudden and uncontrollable fever of speculation if the seal of approval were set officially upon even so sound a stock as Steel common. The delay, however, only encourages reckless plunging by those who think they have discovered a road to easy fortune in American stocks. The regulated stock exchange is better than the bucket-shop, and the pressure of idle money offers opportunity for the shearer of the lambs. Mr. Morgan will win his point, and the result will benefit both France and the United States.

TO BE 'born in Missouri is to be born to trouble', according to an old saw, and it seems to apply to institutions such as the Geological Survey of the State, as well as to individuals. Nowhere else has there been such a succession of storms centering around the office of State Geologist. Yet there have been capable men in the position and work of a high character has been done. The variety and importance of the mineral deposits, the fundamental character of the geological problems to be investigated, and the large areas as yet but little studied, make the maintenance of a survey of more than local

import. In general the State has been willing to have the work go forward, and the appropriations have, on the whole, been comparable to those of its neighbors. While the successive Governors and political powers that be have not been well informed as to the nature and duties of geological surveys, they have, with the notable exception of ex-Governor Stevens, been willing to be advised by those at least presumed to be informed. The whole trouble has seemed to lie in the failure to follow any systematic plan and to secure continuity in the work or permanence of service for the men. Even poorer geologists or engineers than those who have served as Director could have accomplished more if supported in a persistent campaign. The present incumbent of the office, Mr. H. A. Buehler, is an honest and able officer. The present Governor, Mr. Herbert Hadley, is an aggressive exponent of the doctrine of efficient State service. It should be a good time to put the work on the right basis, and to establish the precedent of continuity. There has recently been considerable local, but unfounded, criticism of the Survey. The Legislature properly disregarded it in making appropriations. We hope the organization may now have what it most needs—a period uninterrupted by fault-finding, in which to do some much-needed work.

Coal and Iron in Japan.

Possible Japanese competition in the iron and steel industries, while unlikely for some years, should not be altogether neglected. The iron makers of Japan are in somewhat the same position as are the owners of American seaboard blast-furnaces. They have fuel, markets, and labor, but must in the main import their ore. Little is known as to the iron ore reserves of Japan. Deposits exist near Sakai, Miyako, Minato, and west of Tokyo, but none of these have been much developed. At present the 40,000 tons of pig iron made annually is derived from Chinese ore, which is brought from 200 miles above Hankow. The expense is considerable, and Japanese pig iron in 1907 cost approximately \$20 per ton. That year Japan imported twenty million dollars worth of iron and steel products, and with her best efforts it will necessarily be a long time before local furnaces and steel mills can supply the domestic trade. Eventually it seems quite as likely that the Chinese will work up the iron ores found on the mainland as that the Japanese will do it for them, and indeed at present a certain amount of Chinese pig iron is imported by the Pacific Coast States, and an important Chinese steel-making industry is being established.

In coal mining Japan is advancing more rapidly. As is well known, there are extensive coal fields, both on Hokkaido in the north and Kyushin in the south. It is estimated that the coal reserves amount to 1,200,000,000 tons, and mining is going forward at the rate of approximately 14,000,000 tons per year. The coal beds are well situated for mining, and are 3 to 25 feet thick. Despite these facts, the output per miner is small, approximately 240 tons annually, and the costs are high. The plants are not large, measured by American standards, the most important yielding but a little over a thousand tons per day. Machinery is being introduced for undercutting the

coal, and it is hoped that the cost of production will be reduced. The quality of the coal is not high, though satisfactory for most purposes. The mines already supply a wide trade, which may be reasonably expected to expand.

Civil Service Reform.

The merit system of selecting men and women for the Federal civil service is too well established to be overthrown. Of the 352,000 positions, 206,600 are now filled by appointments based on competitive examinations. The number of places filled by this method is constantly increasing, and the number open to appointment without examination is as constantly decreasing. Any attempt to re-establish the old spoils system may be safely considered to be outside the domain of practical politics. Indeed, the experienced politicians are, generally, friendly to the system. Congressmen soon find that dispensing small patronage produces big quarrels, and while to their followers some may feel obliged to protest against the cruel system which prevents their passing out unlimited clerkships, practically they are many times glad of its protection. The establishment of the present system was a vast improvement on what obtained before; it does not follow that no further improvement is possible. For some years it has been customary for friends of the civil service to regard all criticism as inspired by unworthy motives and as designed to re-establish the spoils system. We believe this to be an error, and the time has come, in our judgment, for a frank consideration of the faults as well as the good points of the competitive examination system. This is especially necessary, since Congress is to be asked next winter to amend the law by extending the power of the Civil Service Commission over promotions as well as appointments. No apology is necessary for directing the attention of mining engineers to this problem, since in contact with the Land Office, the Forest Service, the Reclamation Service, the Geological Survey, and other branches of the Federal Government, they have especial interest in securing prompt, honest, and efficient service. Such service is only possible when good men are selected for the chief positions and are then given a reasonably free hand. They cannot do good work with poor subordinates.

It will be remembered that as the civil service rules were extended to cover each branch of the service, the men then employed were retained. Indeed, many eleventh-hour appointments were made to sweep in under the protection of the rules those who could not have passed an examination. Therefore the public service now contains many who were originally selected for considerations other than fitness. Many of these, after years of comfortable security, have now passed the age when real work is possible. So long as these men and women can sit at their desks the requisite number of hours per day and days per year they are, practically, secure in their positions. By application of the seniority rule many of them have come to positions of at least minor responsibility and are not only themselves a costly burden, but they misdirect the work of others. It is the most

expensive pension system which could be devised, and it is maintained because of a real or supposed popular opposition to civil service pensions; a not unwarranted opposition when the history of our military pension service is recalled. Be that as it may, many a bureau chief at Washington would gladly undertake to vastly improve the work of his office, without extra appropriations, if he could freely discharge or retire on part pay the incompetents he has inherited.

The present system tends toward the accumulation of mediocrity in the departments. The minor positions are over-paid and the more important ones under-paid. The way is easy for really competent young men, particularly those having some special qualification, into and out of Government service. The departments have become great training schools, and many mining companies, railways, and banks have learned to recruit their staffs from the civil service. The school is peculiar, however, in that most of the dull pupils remain in it for life. Some of the very bright ones do also—men of the highest gifts, who prefer, either because of a love of public service, of scientific research, or from a certain timidity respecting uncertainties which Nathaniel Hawthorne long since showed grows with years of such incumbency, to devote their lives to the work. Such exceptional men carry part of the burden of mediocrity with which they are surrounded, but they are not numerous enough to carry it all. This is the explanation of the well known fact that Government work proceeds slower and costs more than does that of individuals or small companies. Timid men shirk responsibility and hide behind rules. From this comes the maze of regulations and red tape.

Conditions of this kind are not peculiar to the Government service. Universities, churches, railways, and large corporations have the same problems to meet. Many of the largest business institutions in America are so new that they do not yet feel the burden. The Government is our largest business, as it is one of our oldest, and the evils mentioned exist therefore in an aggravated form. The placing of all promotions in control of the Civil Service Commission would still further tie the hands of executive officers and intensify the evils of the situation. By exalting seniority it would produce in the civil service the disgraceful conditions of incompetence which the Army exhibited in the expedition to Cuba, and which the General Staff has been so concerned to overcome.

None but competent men and women should be employed by the Government, and to determine their fitness a rigid examination is right and proper. From among those certified to be competent, however, the man in charge should be allowed to select at will, to pay what the service is worth, to promote according to his own estimate of deserts, and to discharge or retire, as the interests of the work demand. By this system honest, efficient service can be secured. After all, it should be remembered that the civil service exists for the purpose of getting the work of the Government well done. In our desire to be just to the employees let us not be led into injustice to the public.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

ROBERT T. HILL is in London.

GEORGE S. TYLER is in San Francisco.

J. W. GREGORY is in Western Australia.

A. E. BARLOW is ill at Montreal, Canada.

F. LYNWOOD GARRISON is in Los Angeles.

W. F. FERRIER has been in San Francisco.

A. S. HOWE has gone to Hillabee, Alabama.

LANE G. GILLIAM has gone to Cook Inlet, Alaska.

POPE YEATMAN has gone to Alaska for the season.

R. J. FRECHEVILLE is on his way to Pachuca, Mexico.

F. B. TRUDE has returned to Kalgoorlie from London.

A. W. SWEET, of Jessup, Nev., was in San Francisco this week.

F. DANVERS POWER has been in Broken Hill, New South Wales.

S. E. BRETHERTON is expected to return from Nevada today.

PAUL M. PAYNE has returned to San Francisco from Modoc county.

F. L. BOSQUI will return to San Francisco, from Europe, in July.

C. C. SHELBY was in San Francisco, on his way to Seattle and Butte.

ROSS B. HOFFMANN is at St. Petersburg, but will return to London shortly.

C. S. HERZIG was in Kansas City, Missouri. He is going thence to London.

E. T. MCCARTHY has left London to examine mines in the Amur region, Siberia.

HORACE V. WINCHELL returned June 25 from a three months trip to Europe.

RICHARD B. STANFORD, of Cape Gracias, Nicaragua, is at Woodcliff Lake, New Jersey.

J. V. N. DORR has returned to Denver, after spending four weeks in New York and vicinity.

HARVEY & WILBRAHAM have been appointed consulting engineers to the Peña Copper Co., Ltd.

ERNEST WILLIAMS has been inspecting the Gwalia Consolidated mine, at Wiluna, Western Australia.

T. NELVILLE has been appointed manager for the Monte Christo mine, at Darlot, Western Australia.

C. HENRY THOMSON has returned to Los Angeles after nearly a year spent in New York and Mexico.

I. L. HOLMAN, of Camborne, Cornwall, was in San Francisco this week, on his way to British Columbia.

C. J. GARVIN has resigned the general superintendency of the Stratton's Independence, Ltd., and is at Paonia, Colorado.

J. K. FIRTH, who was some time ago with the Joshua Hendy Iron Works, has again joined the staff of engineers of that concern.

D. T. BOONE, L. A. JONES, GEORGE GIDUS, and ALBERT S. CARRUTHERS were among those who went into Fairbanks, Alaska, last month.

GERALD LOVELL, recently superintendent of the Great Fitzroy Mines, Ltd., has left Queensland to take charge of the Burma Mines, Ltd., for Bewick, Moreing & Company.

J. B. FLEMING has completed the installation of a stamp-mill for the Mt. Gains Con. Mining Co. at Hornitas, and is now superintendent for the Globe Light & Power Co., at Daunt, California.

S. F. EMMONS sailed from New York July 3 for London, on his way to Leipsic, where he will represent the National Academy of Science at the five hundredth anniversary of the founding of the University.

Dividends.

On Saturday, July 3, 1909, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 142 of \$45,000. This makes the amount of dividends paid since January 1, \$390,000, and the total to date, \$11,061,000.

THE STOCK MARKET has been dull this week, with few sales and generally lower prices. Boston copper stocks have nearly all fallen off a few points, with little demand, those purchasing the stock holding it for its intrinsic value rather than for speculative chances. The Southern Nevada stocks also suffered a set-back on the New York Curb, Consolidated and Combination being decidedly weaker.

General Mining News.

ALASKA.

A large body of placer ground on the Beluga river, tributary to Cook Inlet, is being tested by Lane G. Gilliam to determine its value as a dredging property.—A large vein has been found in the neighborhood of Twelve Mile that is an apparent bonanza. A 12-ft. vein has been traced the length of several claims, samples from which assay as high as \$100 per ton.—A number of parties are working on Alder creek and obtaining good results from the sluicing.—The discovery claim on Dome creek is taking out a fair amount of gold.—At Fairbanks creek water is scarce and most of the work is in preparation for the fall run.—Water is short at Goldstream and the output will be much curtailed this year.

ARIZONA.

COCHISE COUNTY.

Developments in the Junction shaft of the Superior & Pittsburg continue to open more ore. On the 1400-ft. level 50 ft. of 12% sulphide ore has recently been developed. The company is at present pumping 4500 gal. of water per minute from this shaft. At the new Powell shaft, stations are being cut on the 500 and 600-ft. levels. The production of Calumet & Arizona and Superior & Pittsburg was 4,600,000 lb. of copper for May, but is somewhat less for June.—The Shattuck company is shipping a few cars of ore per week to the Copper Queen smelter at Douglas and getting good returns. The orebodies on the 600-ft. level continue to open up well.—A cross-cut from the west drift of the Denn struck 4 ft. of ore that assayed about 12% copper.—The Southern Pacific spur from Pearce to Gleeson has been completed and will furnish an outlet for the ores of the Turquoise district.—W. C. Humphrey has bonded five claims at Courtland from D. W. Brown for \$75,000.—George Woodward has bonded the Nina Blanca property near Wilcox for \$30,000.—The Arizona United Mines Co. is to erect a 125-ton smelter on its property at Johnson at an approximate cost of \$50,000. Wilson H. Brown is manager.—The June output for the Copper Queen smelter was a little over 9,000,000 lb. This is an increase of 10% over last year's monthly production. George B. Lee is superintendent.

GILA COUNTY.

A new head-frame has been erected by the Arizona Commercial Copper Co. and a new cable wound on the hoist. The steel-work of the furnace building is complete.—A new concentrator is being installed by the Cactus Development Co. at Crowley City. A double-drum hoist is on the ground and will be set up shortly at the Hamilton shaft. W. H. Hamilton is mechanical engineer for the company.

MOHAVE COUNTY.

The shaft on the Holy Moses mine, south of Kingman, is being sunk to the 200-ft. level. The ground at the 100-ft. level is much broken, although some ore was found above that level, which was recently tried out in the mill with gratifying results.—The shaft of the Enterprise mine is being sunk to the 300-ft. level. W. J. Martin is the owner.

PIMA COUNTY.

The Imperial Copper Co. in the Silver Bell district is sending about 750 tons of ore per day to the Sasco smelter.—The Southern Arizona Smelting Co. is to enlarge its Sasco smelter. Two furnaces with a daily capacity of 350 tons each are to be added, one of which will be run entirely on custom ore.—The Victoria company, which is operating the old Paymaster mine, is sinking the old shaft from the 320-ft. level. The ore is hauled to the railroad at Twin Buttes and shipped to the smelter. C. T. Roberts is manager. The Esperanza property, under the same management, is making occasional ore shipments.—In the Helvetia district the Helvetia Copper Co. is shipping 60 tons of ore per day to the Old Dominion smelter at Globe. W. C. Steubing is manager.—The old Total Wreck mines, about 10 miles south from Pantano, have been re-opened and the company is developing some high-grade lead-silver ore. The

Southern Pacific railroad is to build a spur to facilitate the shipment of ore.

PINAL COUNTY.

(Special Correspondence).—The Ray Consolidated Copper Co. has commenced grading for a broad-gauge railroad between Ray and Kelvin. The mill is to be built at Kelvin or between Kelvin and Winkelman. The company is to add three churn-drills to its prospecting machinery.—The Ray Central Copper Co. is sinking one new shaft and blocking out ore from the lateral working of the other two.

Ray, July 5.

YAVAPAI COUNTY.

The Lookout mine in the Big Bug district has been bonded to Peter Laux of McCabe. The shaft which is down 150 ft. will be unwatered and sunk to the 250-ft. level.—An important strike has been made at the Little Daisy mine at Jerome. The cross-cut on the 800-ft. level cut three lenses of ore 107 ft. northeast of the shaft that assayed well in copper and gold. J. J. Fisher is manager.—A Burnham sinking pump with a capacity of 1200 gal. per minute has been installed at the Pick and Drill mine in the Bradshaw mountains. Sinking on the vein will be resumed at the 346-ft. level. The 6-stamp mill on the property is kept busy on ore from the development work. S. J. Gnash is superintendent.—The Mudhole mine in the Walker district is now unwatered to the 500-ft. level. The new shaft on the southern end of the property is down 175 ft. and cross-cuts are being run to the vein from that point.—The Champion mine is being unwatered under the supervision of John Edwards.—The Blue Bell mine of the Arizona Smelting Co. is to be unwatered and operations resumed at the Humboldt smelter.

YUMA COUNTY.

A number of prospects in the Winchester district are getting good ore on their properties. A shaft is down 30 ft. on a 3-ft. vein on the Anaconda property.—On the Big Horn property several small shafts have cut ore. W. G. Leftwich, of Phoenix, is in charge of the work.—The Yuma Copper Co. is sinking several prospect shafts.

CALIFORNIA.

ELDORADO COUNTY.

The old Two-Channel gravel mine on the Georgetown divide is to be re-opened. The old company has re-organized and will attempt to work the mine on a larger scale. F. W. Hunton is manager.—The Vandalia mine, four miles below Shingle Springs, was sold by Louis Rosenfeld to Frank P. Merrill and Charles E. Seymour.

INYO COUNTY.

The Birch Creek placer mine has been taken over by C. A. Curl and associates of Riverside. A No. 2 Giant has been installed, 1500 ft. of pipe laid, and the sluices built to handle a large amount of gravel that runs from 20c. to \$2 per cubic yard.—The Casa Diablo Mining Co. shipped two carloads of concentrate to the smelter that assayed \$65 per ton.

MARIPOSA COUNTY.

The Number Five Mining & Milling Co. is sinking its new shaft to the 200-ft. level. At the 100-ft. level a drift was run 300 ft. on the ore and cross-cut driven across the vein 56 ft. A hoist and compressor is to be installed shortly. Hugh Branson is in charge of the work.—The shaft of the old Number Nine mine is being re-timbered to the 250-ft. level and drifts will be run from that point. Richard O'Brien is superintendent. The Quartz Mountain mine under the same management is sinking a shaft on that property.

MONO COUNTY.

Malcolm Macdonald has taken over the property of Tom Neylon in the White mountains under a \$30,000 bond. The claims, 10 in number, are opened by a 1200-ft. adit and join the True Fissure property.

NEVADA COUNTY.

(Special Correspondence).—Sinking at the Empire will start as soon as the new plunger pumps have been placed in first-class working condition. Bonanza ore continues to come from the property, while the 40-stamp mill is operating steadily on ore said to average \$25 to \$40 per ton. George

W. Starr is manager.—Work on a small scale is going on at the Spring Hill.—The 8-ft. vein on the 500-ft. level of the Idaho-Maryland is showing well as developments progress. Bray Wilkins is manager.—It is reported that a 12-ft. vein of \$8 ore has been uncovered at the Mammoth.—The California-Grass Valley Mining Co. has decreased its capital stock from \$300,000 to \$100,000.—The Middle Yuba Hydro-Electric Power Co. is arranging to extend power lines to the Graniteville and Washington districts. This will facilitate the operation of numerous mines at these points that in the past have been handicapped for want of sufficient power.—The geology class of the University of Nevada is studying the formation in the Grass Valley and Nevada City mines. W. S. Tangier Smith is in charge of the party.—With the exception of the pumps, everything is idle at the Murchie mine. Several attachments have been levied against the property.—The work of developing the foot-wall vein at the Champion is progressing. Thirty stamps are in active operation.

Grass Valley, July 6.

A dividend of 4% on its capital stock has been declared by the North Star Mines Co. The sum amounts to \$100,000, which is at the rate of 16% per annum. Last year the company earned sufficient to pay 15%. The shaft is now down over a mile on the incline.—A mill-site for a 20-stamp mill is being surveyed at the Fairview mine. It is hoped to have the mill in operation by fall.—The Red Cross mine in the Washington district has been sold to I. S. Pine and E. J. Dean. There is a 6-ft. Huntington mill and a 20-stamp mill on the property. The adit, now in 400 ft., will be driven 300 ft. more to cut the vein. This will give 250 ft. of backs on a vein that has been from 12 to 20 ft. wide when worked in a large open-cut. The same parties have purchased the Sunshine mine on Poorman's creek. The vein is on a serpentine contact, and varies between 5 and 30 ft. in width. A drift will be run along the vein that will give several hundred feet of backs, and a 5-stamp mill will be erected.—The cross-cut adit at the Oakman mine on Poorman's creek cut a vein that assays between \$15 and \$20 per ton. The vein was 20 ft. wide at the point cross-cut by the adit. Frank Dillon is superintendent.—Ten stamps are dropping regularly at the Ancho mine at Graniteville. George Mainhart is the owner.—The 30-stamp mill at the Erie mine is to be started in a short time.

SAN BERNARDINO COUNTY.

The first carload of ore from the Jumbo mine averaged over \$100 per ton. In the east cross-cut from the 100-ft. level 15 ft. of \$25 ore has been cut.—The shaft of the Oro Belle is down 250 ft. From the 200-ft. level the east cross-cut is being run to cut the Fraction vein and the north drift on the adit level has been driven 300 ft. along a vein of excellent milling ore.—The Acme Mining Co. is erecting a 5-stamp mill at its mines in the Signal Mountain district 20 miles south of Hart and has let a contract to sink the shaft from the 100 to the 200-ft. level.

SHASTA COUNTY.

A 4-ft. vein of good ore was cut in Pierson & Nuser's Milk Maid property near Stella at a depth of 80 ft. The 20-stamp mill is being equipped with electric power.—E. P. and James G. Conner have secured a two-year bond on the Flske-Purcell group 10 miles east of Harrison gulch.—The Mad Ox mine near Whiskytown has been bonded to H. L. Berkey.—The smelter of the Mountain Copper Co. at Keswick is to be enlarged to treat the ores from the Hornet and Iron Mountain mines.

SIERRA COUNTY.

The Colombo mine near Sierra City has been bonded to W. R. Warton of Los Angeles.—Another pocket has been cut in the raise of the Sixteen-to-One mine 50 ft. above the former strike.—The Excelsior gravel mine near Port Wine is to be opened shortly. A channel of pay-gravel is known to cross this claim.—The Gold Standard Mining Co. is driving a drift to open the quartz vein on the Slate Castle-Jaffa claim east of Downieville. J. W. Henderson is manager.—The 12-stamp mill at the Primrose mine in Hog canyon has been started. George Morrison is in charge of the work.—The old adit at the Monte Cristo gravel mine

is being re-timbered and will be driven about 400 ft. to cut the channel. Fred Phelps is superintendent.—W. A. Wood, W. Brusi, and J. R. Van Flat have taken a bond on the holdings of the Bunker Hill Mining Co. between Downieville and Poker Flat and will sink bore-holes to determine the extent and value of the channel.—The Alaska mine at Pike City has been drained and the mill will be started shortly.—The old No. 6 adit of the Sierra Buttes mine is being re-opened.

TUOLUMNE COUNTY.

The Atlas mine in the Jackass Hill district has been bonded by Fred Sutton to R. B. Lucas and Edwin S. Bennett.—L. Baun and L. McRae have taken a bond on the Ida Cline mine. The water has been pumped out to the 60-ft. level and work at that point has opened some high-grade ore.—Work has been resumed at the Never Sweat above Columbia.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work was resumed last week upon the Central Colorado mine on Leavenworth mountain. Charles R. Iliff is manager.—E. F. Byers has secured a lease upon a big block of ground on the Pelican vein, and will work it through the Diamond adit of the Nashotah Mining Co.—The Nashotah Mining Co. is preparing to resume work upon a large scale.—The Mendota Mining Co. is shipping about 60 tons of zinc, 80 of lead, and 125 iron concentrate per month.—A new strike has been made on the Big Indian mine on Leavenworth mountain. A streak from 6 to 10 in. wide assays 2.5 oz. gold and 122 oz. silver per ton, with 10% copper.—J. Nash has been awarded a contract to drive the Prudential adit 200 ft. at the price of \$12 per foot.—A shipment of 20 tons of lead ore was made last week from the Scott mine, which was settled for at the rate of 65% lead and 70 oz. silver per ton.—The Linn Consolidated Mining & Milling Co. shipped two carloads of lead and zinc concentrate during the last week. C. E. Pughe is manager.—The Santiago mine at East Argentine is to double its output shortly, which will raise its shipping product to 150 or 160 tons daily. William Rogers is manager.—C. J. Evans & Co. has taken a lease upon the Doric adit dump and has installed a washer and sluice.—An 18-in. streak of smelting ore has been cut by the adit in the Mountain Queen property at Dumont, which assays from \$55 to \$60 per ton. Fred Pilling is manager.—A small amalgamating mill has been constructed at the Little Flat mine up Ute creek by the owner, C. M. Taylor, of Idaho Springs.—Construction work is under way upon the 300-ton reduction plant at the Alice mine. It is hoped to have the mill ready for ore treatment by September 1. A. H. Roller, of Idaho Springs, is manager.

Georgetown, July 3.

EAGLE COUNTY.

The Gold Curve Mining Co. has been incorporated to work the placer deposits of the Grand River country near its north line. J. C. McClintock is at the head of the company.—Two new pumps have been installed at the Champion lease and the mine unwatered.—At the Enterprise in Eagle canyon a compressor plant is being installed and a drift will be run along the vein. Thomas Keating is in charge of the work.

GILPIN COUNTY.

The Daisy mill has been started crushing ore from the Burnell property on Perigo hill. Al Bailey is in charge.—Potter & Lightbourn have started the Perigo mill on the Perigo and Comstock ores.—A contract has been let to drive the main adit of the Penobscot property. A test lot of ore from the McCartney vein assayed well in copper and gold.—A new boiler has been installed in the Evergreen mill and a hoist to raise the ore from the old dump to the ore-bins.—Development work has been started on the Seabird group in Moon gulch.—The Mountain Monarch Mining Co. has resumed operations at its mine in Gamble gulch, with M. S. Shanks for superintendent.—E. M. Green shipped a car of tungsten ore from Camp Manchester to the Nederland mill.—H. P. Lowe and S. T. Harris are operating the Rockford mine in Russel gulch.—A new

water-skip has been installed at the Pewabic mine.—The Aztec Mines Co. has installed an electric pump on the 620-ft. level of the O. K. mine.—A 5-drill Rand compressor was delivered to the Pearl Tatum Mining Co.—Westcott, Leverton & Co. received \$125 per ton for a small shipment of ore from the Russell mine.—The Gregory vein has been opened at the 1400-ft. level by the Fifty Mines Co. and drifts run along it for 50 ft. in each direction. The mill is handling from 150 to 200 tons of ore per day.

LAKE COUNTY.

The Tribune lease, which is being worked through the Yak adit, has cut 100 ft. of ore. L. R. Johnson and T. M. Howell are the owners of the lease.—The Matchless lease is shipping regularly from the No. 6 and No. 7 shafts. Lessees on the old Chrysolite mine on Fryer hill are making regular shipments.—The mill at the Lillian mine on Printer Boy hill is crushing ore taken out by lessees. Wallace Murcay holds a general lease on the property. John Withney has a lease on the dump and is working about 150 tons per day.—The Houston adit, which taps the Ella Beeler, Little Alice, Ready Cash, and other claims, is leased to A. S. Sharp.—The Helena mine is to be re-opened shortly.—An 32-hp. motor has been installed to run the hoist at the Valley shaft in Big Evans gulch. Warren F. Page is manager.—George Bennett, David Harris, and C. A. Edwards are shipping 50 tons of ore per day from their lease on the Hibschie and Coronado mines.—The Yankee Doodle property on Carbonate hill is shipping one carload of smelting ore per day.

SAN JUAN COUNTY.

A compressor and engine is to be installed at the Hermes mine near Animas Forks. H. M. McGrew and F. D. Fowler are the principal owners.—The Danville Mining Co., operating a lease on the Shenandoah mine, has completed its new ore-bins and is shipping regularly.—The mill of the Gold Prince, which was injured by a snow-slide last winter, is being repaired and enlarged. Several Card tables have been added to the equipment. J. O. Campbell is in charge of the work.—The Koehler adit of the San Antonio Mining Co. is being driven to cut the vein at a point that will give 500 ft. backs. M. T. Chestnut, of Denver, is president.

SAN MIGUEL COUNTY.

A dividend of 48c. per share has been declared by the Tomboy Mining Co.—At Ophir loop the Butterfly mine is being operated by the Buckeye Leasing company. The mill is crushing 80 tons of ore per day.—The dump of the Smuggler-Union, which averages about \$8 per ton, is being worked by lessees, their rock being crushed in the old mill. The new mill has been idle this winter, owing to an excessive amount of water in the mine, but will be started early this month.—The King mill and cyanide plant is to handle the ore from the Summit lease.—The Waterfall mine near Ophir shipped a carload of ore to the Salida smelter that assayed \$19 gold, 95 oz. silver, and 48% lead per ton.—At the Black Bear mine cross-cuts are being driven to tap the Bradley and Smuggler veins. Oscar Mantyla is president of the company.

SUMMIT COUNTY.

The Central Colorado Power Co. has contracted to supply the Hamilton mine with electric power by the 15th of this month. An adit is to be driven near the Swan river that will give 1200 ft. of backs on the Hamilton and Action groups.

TELLER COUNTY.

The Robert Burns mine on Guyot hill, adjoining the Katinka Gold Mining Co.'s estate, has been leased by Newt Wilson, manager of the Robert Burns Mining Co., to George Hawkins and associates of Cripple Creek, and the Jay Bird and Maid, two fractional claims on Bull hill, containing about four acres, adjoining the War Eagle and Ramona mines, have been leased to R. G. Harrison, of Colorado Springs. The leases on both the Bull and Guyot hill properties cover a two-year period and the lessees will pay a graded royalty of from 15 to 30% on all ores marketed.—A three-year lease and bond has been secured on the North Cascade claim on Beacon hill by A. Norden.—A new lease has been granted to the Clements Leasing Co. on the prop-

erties of the Gold Sovereign Mining & Tunnel Co. Heavier machinery will be installed and development started on the 1000-ft. level. W. H. Clements is manager.—The return on 26 tons of ore shipped from the 300-ft. level of the Aileen mine on Raven hill was \$32 per ton.—A small sacked shipment containing 1254 lb. mined by George Morrison from a block of ground at the 100-ft. level of the American Eagle mine was settled for at the rate of 59.54 oz. gold per ton.—Prospect work has been commenced at the main shaft of the Gold Sovereign by W. H. Clements.—Lessees have cut a new ore-shoot in the Coriolanus mine on Battle mountain. A test lot was shipped, and if the run proves successful more will follow.—E. J. White, leasing on the World's Fair mine on the southern spur of Gold hill, owned by the Gold Bond Consolidated Mines Co., is shipping ore carrying 2 oz. of gold.—Due to extensive development work the production made from the Modoc mine, in the saddle between Bull hill and Battle mountain, was unusually light last month, but it is understood that new orebodies have been disclosed and the July production will show material increase. Two cars were shipped from the mine and consigned to the Eiler smelter at Pueblo, the ore being estimated at 2-oz. grade.—Work has commenced on the excavations and road-bed at the site of the new mill to be constructed by the Portland Gold Mining Co. on Battle mountain for the local treatment of such low-grade ores as will not pay for the transportation to the mill of the company at Colorado City. The plant is to have an initial capacity of 300 tons per day, and will be so constructed as to permit of enlargement. The mine is shipping between 200 and 250 tons per day to the Colorado City plant, and this tonnage will be maintained.

IDAHO.

IDAHO COUNTY.

The old shaft of the Independence group is being unwatered and sinking will soon be resumed. Some good ore has been found on the old vein. J. Rogers is in charge of the work.—Two large cyanide tanks are being added to the Buster mine equipment.

KOOTENAI COUNTY.

The Knickerbocker Mining Co., operating the old Charles Dickens mine in the Coeur d'Alene district, has sent two cars of ore to the smelter at Tacoma and is getting out 90 tons for a second shipment to be made this month. A. D. Gritman is manager.—A shipment of ore from the upper workings of the Silver Cliff Co.'s property assayed 23% copper, 35 oz. of silver, and \$15 gold per ton.—The Granite and Allie claims will ship concentrate as soon as the 10-stamp mill can be converted into a 40-ton concentrator. The mill was planned for a free-milling ore, but the character of the vein changed to lead-silver with depth. The vein is 32 ft. wide with 24 ft. of concentrating ore.

NEZ PERCE COUNTY.

The drift in the lower level of the Silver Cliff near Look-out has cut some 2% copper ore. James D. Young is manager.

OWYHEE COUNTY.

E. I. Field, of Denver, has bonded the Empire claims on War Eagle mountain.—The adit of the Banner mine is in 1300 ft. and has cut some stringers of quartz. Peter Steele is manager.

SHOSHONE COUNTY.

The face of the drift on the Torino group is in ore that assays well in copper and gold.—The cross-cut adit of the Helvetia property, near Wallace, cut a small vein of shipping ore. The adit will be driven 60 ft. to cut the main vein.—The cross-cut on the Coeur d'Alene Vulcan property is in 850 ft. and has cut a number of small veins of galena ore.—The Butte & Coeur d'Alene Mining Co. is to sink a 500-ft. double-compartment shaft and cross-cut to the vein at the 200 and 400-ft. levels. James Quinlan is manager.—The Caledonia mine at Wardner sent five cars of ore to various smelters in June with satisfactory results. The ore was extracted from the cross-cut 300 ft. from the surface.—The drift on the Star property near Mullan opened a 7-ft. shoot of lead-silver ore.—The Lucky Calu-

met Copper Co. has let a contract to John H. Nordquist to drive an 1800-ft. cross-cut on its property near Mullan.

MICHIGAN.

The Winona Copper Co. has let the contract for the structural steel that will be used in the construction of the mill, and it is expected that the first of the steel will be delivered in about 90 days. The completion of the excavation work will be followed immediately by the laying of the mill foundations. Operations in the mine continue centered in opening work, with uniformly good results, particularly to the southward. The mine is opened fully five years ahead of requirements and in shape to begin producing at the rate of 1000 tons of ore per day. The mill is expected to be in commission by June 1910.—The Lake and North Lake companies are arranging to begin diamond-drilling jointly, each bearing half of the expense, near the boundary which separates their properties. The results of such an undertaking will be the finding of the extension of the Lake lode northward from the Lake mine and southward from the North Lake's present diamond-drill work. The proposed point of operations will be about 4500 ft. north of the Lake shaft. The fourth level in the Lake, now run about 20 ft. each way from the cross-cut that exposed the lode, is opening first-rate stoping ground. It is not as rich as the remarkable ground exposed at the third level, but is considerably richer than the average amygdaloid of the district.

MONTANA.

BROADWATER COUNTY.

The south shaft on the property of the Ohio-Keating Mining Co. is being re-timbered and will be sunk from the 125 to the 225-ft. level. A drift has been run 90 ft. from the 120-ft. station. Ore taken from the 120-ft. level of the north shaft assayed \$64 per ton and surface samples taken to the north of this shaft ran from \$30 to \$78 per ton. The ore carries a high percentage of iron and makes an excellent flux for the smelters.

SILVER BOW COUNTY.

The Butte Central Copper Co. is moving its boilers near the shaft and adding another boiler to the battery preparatory to unwatering the Ophir mine and resuming development work. The company proposes to build a concentration plant to treat the vast quantity of low-grade silver and copper ore in its upper workings, while sinking the shaft deeper and opening the lower levels.

NEVADA.

DOUGLAS COUNTY.

A 40-ton centrifugal mill has been installed by the Pine Nut Consolidated Mining Co. near Gardnerville. The plant is now equipped to crush and cyanide about 60 tons per day.

ESMERALDA COUNTY.

(Special Correspondence).—The Gold Reef lease on Queen Bethania is sinking a new shaft on the Bridge-Daniels vein. A 4-ft. streak near the surface assays \$6 per ton.—The Lawyers lease on Bethania Mines ground is sinking the shaft to the 100-ft. point. As soon as the new hoist has been placed the shaft will be crowded rapidly. A 14-ft. body of \$12 ore has been opened.—Several claims that have laid idle for months are again being worked. The good showing of Queen, Coalition, Bethania, and one or two other mines is doing much to justify the early predictions regarding Rawhide, and the operation of several mills is also aiding developments.—The Lodi Mines smelter at Luning has been blown in and is receiving ore from several points. Mines that have laid idle for years on account of lack of milling facilities are taking on a new lease of life.—The Gold Mountain district, south of Goldfield, is attracting considerable attention. The Mammoth company has opened large reserves of ore and is building a 35-ton plant.—The Nevada Empress has opened several veins running about \$25 per ton. It is planned to increase the capacity of the plant.—The Great Western has been acquired by Philadelphia people. New machinery will be installed and the mine operated extensively.

Rawhide, July 5.

The raise in which the rich strike was made at the Golden

Daisy lease at Diamondfield a short time ago continues in good ore. The lease covers a block of ground 300-by 600 ft. 800 ft. from the main Daisy workings and runs for three years. H. A. Morrison owns the controlling interest.—The cross-cut from the 400-ft. level of the Mint lease at Rawhide struck a good body of ore.—The shaft on the Miller lease is to be sunk to the 200-ft. level and drifts run from that point.—On a 98-ton shipment from the Truett lease to the Murray mill the return was about \$30 per ton.—The Grutt-Balloon Hill lease shipped 50 tons of ore that assayed \$2000 per ton.—The Marigold lease is shipping 25 tons of ore per day that mills between \$18 and \$30 per ton.—The McCormick lease on the Lucky Boy claim is shipping about four cars of ore per week to the Salt Lake smelters. J. C. McCormick is the principal owner of the lease.—A 4-in. vein of lead-silver ore has been opened on the property of John Miller on Mt. Corey, 8 miles from Luckyboy.

HUMBOLDT COUNTY.

The old Arizona mine at Unionville has been sold. The high-grade ore will be shipped to one of the Shasta county smelters and the low-grade stored for the mill which is being re-built and enlarged. The sale was made through H. D. B. Haysted, of Lovelock.

NYE COUNTY.

(Special Correspondence).—While people continue to pour into Elendale, developments have not been of such a nature as to encourage the disgusted arrivals. Surface indications are excellent, but the Cliffords, the original locators, are doing nothing to prove the persistence of the orebodies. Despite the extravagant claims made by the Cliffords, they have not sunk even a 10-ft. shaft, and seem disposed to have someone else risk their money in such an enterprise.—It is reported that the Bullfrog Gold Center Mills Smelting Co. will erect a 250-ton smelter before the end of the year. The company controls 400 acres of placer lands and several quartz properties.—It is unofficially reported that the original Pioneer lease has posted a dividend of 5c. per share and that others will follow unless operations are stopped by litigation.—Excavating and grading for the new Tonopah Extension mill is progressing rapidly. The Union Iron Works of San Francisco has been awarded the contract for supplying 30 stamps, mortars, cam-shafts, ore-feeders, etc.—The Montgomery-Shoshone mine is producing at the rate of 210 tons per day. The June yield was approximately 6800 tons. Owing to the breaking of the dam at Bishop the mine and mill were idle for two days because of lack of power. Cross-cutting and driving from the 400-ft. level is progressing.

Tonopah, July 3.

A dividend of \$32,000 was paid by the Round Mountain Mining Co.—The Lemon mill and cyanide plant has been leased by Eugene Howell, Gilbert C. Ross, and L. L. Nushett to handle the ores from the Manhattan-Thanksgiving, Earl, and Gold Crater claims.—Lateral work from the 100-ft. level of the Keane Wonder has cut 40 ft. of milling ore.

WHITE PINE COUNTY.

A 3-compartment shaft is to be sunk to the 600-ft. level on the Eureka Fraction claim of the Ely Central group. The shaft will be within 600 ft. of the pit, as good ore has been cut by bore-holes within that distance. O. A. Turner is in charge of the work.

UTAH.

BEAVER COUNTY.

The Utah Mining, Milling & Transportation Co. is to sink a new double-compartment shaft to the 200-ft. level and cross-cuts run to the orebodies from that point. The company has recently acquired the Lady Bryan property from Cullen & Moritz. Charles T. Birchard is president.

JUAB COUNTY.

At the Provo property of the East Tintic Development Co. a cross-cut has been started from the 300-ft. level to tap the orebody.—The new shaft of the Tintic Standard is down 125 ft. Oscar Radditz is superintendent.—The Chief Consolidated is now making small shipments regularly.

SALT LAKE COUNTY.

The property of the Emma Copper Co. at Alta has been attached by the Utah Mining Machinery & Supply Co. for a bill of \$1100.—The shaft of the Last Chance mine in the Big Cottonwood district cut a 6-in. vein of lead-silver at a depth of 70 ft. W. P. Worthen is manager.—A contract has been let to W. T. Quinn to drive 100 ft. of adit on the Old Glory property.

SUMMIT COUNTY.

The shaft of the American Flag mine is down 1100 ft. with considerable development work on each level. Howard P. Saunders has been examining the property to determine the best form of mill to be erected on the property.

UTAH COUNTY.

The cross-cut adit of the Mineral Flat mine in American Fork canyon is in 1300 ft. This is being driven to cut a vein of galena ore on a lime and porphyry contact.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—During the lease of the Insurgent mine, which terminated recently, 671,892 tons of ore was shipped to the smelters, which assayed 1.21 oz. gold and 6.65 oz. silver per ton. The entire gross value of the output was \$18,477.—The lessees of the Lone Pine claim of the Pearl Consolidated Mining Co. have cleaned out the old Jim Clark adit and will drive it 175 ft. to intersect the No. 4 Lone Pine vein 80 ft. below the old workings, from which considerable rich ore was extracted in former days. The lessees have shipped eight carloads of ore to date from the main Lone Pine vein.—The lessees of the San Poll mine have installed a new 3-drill compressor. They have shipped three carloads of ore and expect to ship a carload per day, as soon as the New Republic Co. can furnish power.—The New Republic Co. has started its electric plant and is preparing to furnish power for the Republic, San Poll, and Black Tail mines.—Some fine ore is being extracted from the surface working of the Ben Hur mine.—The Colville Mining & Smelting Co. has resumed work on the Mountain Boy, Summit claims, and smelting plant, at Park City camp, with William M. Crummer as superintendent.—A 7-hp. gasoline engine has been installed at the Advance mine in Meteor district, to be used for driving a fan, hoisting, and pumping from the winze which has been sunk in the ore.—A test shipment of ore from the Longstreet mine has been sent to the smelter from Covada camp.

Republic, July 5.

STEVENS COUNTY.

The Imperial Copper Mining Co. is installing machinery at its property near Chewelah under the supervision of P. J. Bonner.

CANADA.

ONTARIO.

The Coniagas Mines Co. is to double the capacity of its mill by adding 30 stamps. This will handle from 150 to 160 tons of ore per day and produce about 4 or 5 tons of concentrate. The outlay for the additional facilities will be approximately \$40,000.—The Kerr Silver Mining Co. at Peterson lake cut an ore-shoot in the south drift 85 ft. from the 125-ft. level of its shaft.

BRITISH COLUMBIA.

A rich body of carbonate ore has been cut in the Whitford & Jenkins lease on the Blue Bird mine in the Slocan district. The ore assays well in silver and gold.

MEXICO.

DURANGO.

The report of Frederick Stallforth, president of the Mexico Consolidated Mining & Smelting Co., shows that the old debt has been paid off, a new cyanide plant installed, and a large quantity of milling ore opened on the seventh and eighth levels. J. J. Welsel is consulting engineer for the company's property at Guanacevi.—The Boca del Cobre mine in the Nazes district is working on a body of ore 20 ft. wide that averages about 5% copper and 90 oz. silver per ton. The property paid \$20,000 net during June, and

will pass \$25,000 in July. The ore being opened on the fifth level is better than that previously worked, running between 5 and 6% copper and over 100 oz. silver per ton. The shaft is being sunk below the sixth level and the station cut at that point.

SONORA.

The Silver Seal Mining Co., which owns 325 acres near Nacozari, struck a good body of ore in its cross-cut adit. The ore is being shipped to the Copper Queen smelter at Douglas.—The El Van Copper Co. is doing about 500 ft. of development work monthly. Fritz Kohlmeier is manager.—The Ey Aguaje mine, of the Ey Aguaje Mining Co., is being unwatered.—The La Carida mine is opened so that ore shipments can be resumed any time the company wishes to do so. A. L. Godbe is in charge of the work.—The Dawson Mining Co. has ceased operations at its Creston de Oro property.—The Banco de Sonora of Hermosillo has taken over the Lampazos group of mines under a mortgage held by them for \$800,000.—Cross-cuts from the 200-ft. level have been run to the orebodies of the Monte Cristo mine of the Moctezuma-Duluth Development Co., and opened ore that runs 700 oz. silver per ton, which is being shipped to the Arizona smelters.—The Washington mine of Bostwick & Dickson is reported sold to the Calumet & Arizona Copper Co. for the sum of \$250,000.—The Minneapolis Copper Co. has resumed operations under the management of Tom L. West.

PHILIPPINE ISLANDS.

Strikes of good ore are reported from the Paracale district in the Camarines province and from the Baguio dis-

Philippine Islands.

trict in the Benguet province. Both properties are doing development work on quartz veins along which surface work has disclosed some excellent ore. A dredge has been working in the Paracale district for the past year and two more are soon to be constructed.

Special Correspondence.

LONDON.

Radium Developments.—Phoenix Tin Mine.—Great Cobar.

The British Metalliferous Mines, Ltd., has contracted with the trustees of the British Radium Institute, recently founded for medical research, to supply $7\frac{1}{2}$ grams of pure radium bromide, at the price of £4000 per gram. The company owns the celebrated uranium mine at Gram-pound Road in Cornwall, which has been producing pitchblende for a great many years and selling it for its uranium value. This present deal is the first in which English pitchblende has been sold for its radium value. The actual extraction and production of the radium bromide will be done by Buchler & Co., Braunschweig, Germany. I am also informed that the St. Ives Consolidated, which owns the Trenwith mine in Cornwall, will shortly enter the market with radium. Sir William Ramsay has been conducting extensive experiments on the Trenwith ore. He has recently elaborated an improved method of extracting the radium content, and the St. Ives company has determined to adopt the process.

The Royal Family are considerable landowners in East Cornwall and Devonshire and in several of the districts they are also the owners of the mineral rights. A fortnight ago the Prince of Wales, in whom the title rests, paid a semi-state visit to the Phoenix mine near Leskeard. This mine has been requiring further funds for development for some time, so the Prince's visit was opportune. The mines were worked for many years until 1897, when the decrease in tin content of the ore, combined with the low price of metal, made it necessary to close down. A few years ago the Cosmopolitan Proprietary, until then identified with West Australia, acquired the property and spent large sums of money in re-opening it. The mine has this week been floated as a separate company with a nominal capital of £160,000, of which £60,000 in shares goes as purchase price to the vendors, the Cosmopolitan company, another £60,000 is being subscribed in cash by the vendor company and its friends, while the remaining £40,000 is being offered for public subscription. A new main shaft is being sunk to the 1020-ft. level, where the old workings ended, and machinery is being provided. The prospectus is not as clear as it might be. The output for the years 1877 to 1897 is given, and the average recovery over these years, 36 lb. of black tin per ton, is taken to be the average for the future. In addition an extra 20% recovery due to improved plant is assured. On looking at the returns for twenty years it is evident that the decline has been steady: In fact, during the years 1877 to 1887 the average production was 44 lb. per ton, but since then it has steadily and regularly dropped until it was only 27 lb. in 1896 and 1897. It seems, therefore, that 36 lb. can hardly be counted on for the future. However, there is no reason why 27-lb. ore, if found in quantity and treated in a modern way, should not earn substantial returns.

There has been considerable wonderment in London as to why the Great Cobar has not done as well as was expected. This mine, one of the best known producers of copper in Australia, was floated in London over two years ago, and last year the new smelters were put into commission. This smelting plant was as up-to-date as possible, and was supplied by an experienced American house, but kept breaking down. It became necessary for the consulting engineer, J. D. Kendall, to proceed to the spot six months ago. He has just returned and is very severe on G. H. Blakemore, the general manager of the company, for the failure. I do not intend to quote details, as I have not heard the other side. It may not have been the fault of the general manager. It may have been the absence of a smelter manager. Anyway, it appears that the three great blast-furnaces all went wrong, and the settlers as well. The company has appointed H. C. Bellinger, of Salt Lake City, Utah, formerly with the Bingham Consolidated Mining & Smelting Co., to take charge of smelting operations, and the plant is now getting into better shape.

WASHINGTON.

European Zinc Trust.—Tariff on Oil, Monazite, and Tin.—Monazite Sands in Brazil.—German Competition.

H. A. Johnson, American Consul at Liege, Belgium, has written concerning the formation of a European zinc trust. He declares that an international agreement has been concluded between a number of prominent zinc works, resulting in the organization of what is designated as the 'Syndicat des Usines a Zinc'. The Consul says: "The limit of production of each of the firms having been established, the principal clause of the agreement stipulated that should the current price of zinc fall below \$92.46, or should the accumulation of stocks show an unusual increase, production would be proportionately reduced. If, on the other hand, the current price of zinc continues to be above \$92.46, this limit of production may be increased as arranged in virtue of an agreement between delegates from each group of concerns making up the trust, which includes German, Belgium, and English concerns, although it seems that agreements have not yet been concluded with the last mentioned. It is asserted that the works of H. G. von Giesche, a concern that is said to produce one-fifth of the total output of the zinc in Silesia, are not included in the new combine, whose main object is to regulate production, but competition from this quarter apparently is not feared. Steps have been taken to induce the five most important zinc works in England to join the trust. As to the zinc works of the United States, it is believed that anything like extensive exports of zinc from that part of the world are too far in the future to need serious consideration at the present time. It is rumored that one of the earliest results of the formation of this trust will be an increase in the present price of zinc, such an advance having already been definitely decided upon." A supplementary report states that the syndicate was organized as a limited liability company. The capital is said to be \$509,400, and the management is placed in the hands of the director-general of the Hohenlohe works. The sale of zinc will be effected through the agency of Beer, Sondheimer & Co., the Metal Gesellschaft of Frankfurt-on-the-Main, and by Aaron Hirsch, of Halberstadt.

The surprise of the extraordinary session was the defeat of the amendment to the tariff bill proposed by Boise Penrose, Senator from Pennsylvania, placing a duty of $\frac{1}{2}$ c. per gallon on crude petroleum. It was practically agreed that the independents had made their case and that they would get a duty on the crude petroleum, but when the vote was taken in the Senate, the independents had lost by 40 to 34. At the instigation of W. B. Heyburn, Senator from Idaho, the Senate adopted an amendment to the tariff bill placing a duty of 6c. per pound on monazite sand and thorite. Another amendment, prepared by the same Senator, was adopted as follows: Thorium, oxide of and salts of, 60% ad valorem. Gas mantle scrap, consisting in chief value of metallic oxides, 20% ad valorem. Thorium, it was explained to the Senate, is used in the manufacture of incandescent gas mantles and is extracted by chemical process from monazite sand. This sand is found in commercial quantities in Brazil and the United States, a German concern controlling the industry in the former place. Importers and mantle manufacturers offered their protest to the Senate against the imposition of a duty on the sand. This brought out a reply from Alexander P. White, vice-president of the National Light & Thorium Co., which to a degree was startling. Mr. White, under oath, charged that the German concern lowered the price of thorium from \$6 per pound in 1905 to \$3.50, with the purpose of injuring the American company. This caused the company to suspend business, and then the price went up to \$4.80, at which price it remained until the publication of the Payne tariff bill. Thereupon the price was again reduced and the material sold at prices varying from \$3.40 to \$3.70, which is less than the cost of production in the United States. Robert J. Gamble, Senator from South Dakota, introduced an amendment providing for a tariff upon cassiterite, and upon bar, block, and pig tin, a duty of 4c. per pound when the mines of the United States are producing, and will continue to produce 1500 tons of tin in cassiterite or of pig tin per year.

MEXICO.

Guanajuato. — Gold Increase with Depth. — La Pastita. — New Construction. — Real Del Monte Dividends. — Revival at Zacatecas.

The combined bullion, concentrate, and rich ore production of Guanajuato continues gradually to increase, until it is now some twenty thousand in excess of the quarter million peso mark per week, and there is also a marked increase in the gold content of these shipments. There seems to be a slight increase in gold in the ores as deeper working is attained, though the largest gold yield is obtained from the new producers and from those on the outer edge of the district where the cross-vein system is strongest. The Carmen, Pinguico, and Peregrina are included in the list. This latter, being one of the Guanajuato Development Co.'s properties, is treating at its new mill with great success from 14,000 to 15,000 tons per month. Some 11,000 tons of this comes from the mine and the remainder from the dumps. The resulting bullion has about 70% of its value in gold. The Peregrina is showing better than ever. The Guanajuato Consolidated Mining & Milling Co. has now 100 stamps dropping at its San Francisco mill in La Pastita, and with the filter-press just completed will be enabled to greatly increase its tonnage. This company showed for 1908 a surplus of \$32,080 above its regular dividends, and its annual report stated that \$68,495 was paid to the Federal Government in taxes of various kinds. At El Cubo mine, one of the farthest outlying properties, which has been all but closed for some time because of expensive handling and unsatisfactory extraction, the tunnel has been completed and surface trams are being installed to run direct from the tunnel to the mill and new cyanide tanks. On completion of these, production and extraction will be again resumed, when it is believed that the economy of tunnel, and alterations in the cyanide plant, may put this old property once more on a paying basis. The San Cayetano is being rapidly unwatered by the Lewisohns and will soon be placed among the shippers. The Santa Natalia new 100-ton mill is up and working and is giving excellent returns. The new mill is rapidly nearing completion on the Carmen. At the properties of the American Mining & Milling Co., at the Corwin & Greene group, at the Robles mine, and at the Letitia M., there is promise of early and large production. George W. Bryant, of the Guanajuato Development Co. is planning a great deal of new work in La Luz district before the end of the year. Norman Rowe, of the Guanajuato Electric Light & Power Co., is stringing his wires as rapidly as possible in all directions. He has but just completed the line into San Gregorio, and is giving light and power to Silao. One cannot help marveling at the changes which have been wrought at Guanajuato in the last few years. The rejuvenation of Guanajuato is almost wholly due to the introduction of American capital, the cyanide process, and electricity. The same applies to Pachuca, recent manifestations of the results of which are the dividend just paid by the Real del Monte Co., of Pachuca, of \$100 per share on 2554 shares, making \$870,000 paid by that company in dividends this year. Seeing what had been done in the old camps of Guanajuato and Pachuca, and knowing the immense low-grade deposits in the famous old camp of Zacatecas, one could not help prophesying that Zacatecas must soon follow in the footsteps of the other two. The rather complex character of the Zacatecas ores, however, from a clean quartz to a heavy sulphide, and the belief that the cyanide method was limited in its application, delayed the change in Zacatecas. The El Bote mine, one of the oldest producing properties in the district, with its new mill has blazed the trail for the cyanide treatment at that place. Awakened by the results at El Bote, a number of prominent business men of Zacatecas, under the guidance of Marcelino Velasco Peña, have organized a company and subscribed for the erection of a modern and complete testing plant, wherein may be conducted experiments on all the various ores of the camp on a working scale. It will not be a custom mill, but a testing plant on a large scale, for the benefit of the whole camp. The erection and completion of this plant means much to Zacatecas. The general impression is that on the clean dry ores economical results may be ob-

tained on as low a grade as 350 grams (10 oz.) per ton, or even lower. Of such ores there are thousands of tons on the dumps and in the old mine workings. With the success of these experiments there lacks only the introduction of electricity to make Zacatecas great.

BUTTE, MONTANA.

June Production. — Amalgamated Management. — Flathead Placers. — Polaris. — Bear Gulch. — Princeton District.

The monthly copper production of the Butte companies for June reached about 25,548,880 lb., with operations averaging 28 days during the month. The total average daily production was 912,460 lb., and the tons of ore mined during the month amounted to 352,100. The returns for the various companies are given below:

| Companies. | Daily Lb. per | | Total lb. |
|---------------------------|---------------|------|------------|
| | tons. | ton. | |
| Boston & Montana | 3,510 | 75 | 7,371,000 |
| Anaconda | 3,530 | 65 | 6,424,600 |
| Butte & Boston | 630 | 63 | 1,391,320 |
| Washoe | 530 | 61 | 905,240 |
| Parrot | 390 | 58 | 633,360 |
| Trenton | 400 | 59 | 660,800 |
| North Butte | 1,325 | 90 | 3,339,000 |
| Butte Coalition | 1,310 | 77 | 2,824,360 |
| Original | 550 | 76 | 1,170,400 |
| Pittsburg & Montana | 300 | 72 | 604,800 |
| Miscellaneous | 100 | 80 | 224,000 |
| Totals | 12,575 | | 25,548,880 |

John D. Ryan, who is in Butte this week, states that the management of the Amalgamated properties will proceed in the future much as they have in the past. Mr. Ryan also stated that Ben B. Thayer, the newly elected president of the Anaconda Copper Co., will continue to visit the city.

A. J. Davis, Charles J. Kelly, and Mel Lowery have become interested in placer gold mining in Flathead county. Harry Armstead, Jr., of New York, manager of the Silver Fissure Mining Co., which owns a mine and smelter at Polaris, Montana, visited the company's property last week. A spur is to be constructed from the nearest point on the new Gilmore & Pittsburg railroad, on Horse Prairie, to Polaris, and in consequence it is anticipated that the camp will experience a boom within the next few months. The Bear Gulch district of Madison county is the scene of much activity this summer. It is rich in lead and copper, and it was here that one of the first efforts at lead smelting in Montana was made. A consolidation of properties, in which Alex Johnson and the Moffat brothers are interested, is said to be impending. Several experts have visited the ground this summer and made examinations. In the same district Bert A. Tower and Bert Plum have erected a small cyanide mill on what is known as the old Bausch property, and are mining and treating the ore. The Stewart boys of Butte have a lease and bond on a property in the same gulch, and in a 300-ft. adit have cut a vein 30 ft. wide, 10 ft. of which is good shipping ore and 10 concentrating ore. They are now improving the old concentrator on the property by the addition of Wilfley tables, and will also put in an air-compressor.

In the Princeton district of Granite county, 60 miles west of Butte, some important work is being done. On the Gold Hill property, owned by a number of Butte men and bonded to a man named Bradley, a vein of free-milling gold ore assaying \$12 to \$15 per ton has been found. In the same district and on the South Boulder creek, the old Brooklyn mine has been shipping ore during all of the past winter. It is an old-time silver-lead producer, and is owned by Whitworth, Garron, and New, of Phillipsburg. Three shoots of ore, 35 ft. thick and of indefinite length, have been discovered, and a winze is now being sunk on ore which will average 1000 oz. silver per ton. The Northern Belle, near Princeton, is being opened for a syndicate of Seattle men, but the work is somewhat delayed by water. Arrangements are being made for the construction of a mill. All of these properties in the Princeton district are in the vicinity of the once famous Granite Mountain and Bimetallic properties.

JOHANNESBURG, TRANSVAAL.

Simmer Deep Mill.—Caldecott Filter Tables.—Mineral Output.

On May 22 the members of the Chemical, Metallurgical & Mining Society visited the plant of the Simmer Deep, a mine as well known for the excellence of its milling and cyanide works as for the lamentable poverty of its ore reserves. The percentage of unpayable rock developed is apparently such that the directors have not the courage to make a clear statement as to the full results of development. But what the Consolidated Gold Fields lack in this connection is well compensated for by the very high efficiency of their metallurgical and mechanical departments. The Simmer Deep and Jupiter joint mill of 300 heads has given W. A. Caldecott and Hans Behr an opportunity of putting into practice the latest ideas in the construction and operation of reduction plants, without obstruction by existing units or by limitations of space. The mill, which is at present of 300 heads, involves many new features. The mortar-boxes rest on cement foundations, with a $\frac{3}{8}$ -in. rubber cushion and no anvil block. Stamps are weighted up to 1650 to 1700 lb., and each battery of 10 stamps is driven by an independent 50-hp. motor. The mill-bins are flat-bottomed and of 7000 tons capacity, and the ore is fed into the mortar-boxes by means of 'Nelson' grip feeders. There is back-water feed. In the construction of the battery and mill building an exceptional amount of iron and steel is used. In the original design of the plant, which has been laid out with special attention to the requirements of speedy extension, the classification of the mill tailing for the tube-mill circuit, sand and slime plant was to have been effected in the usual spitzluten. Changes have been made at this stage of the process, and these prove the most interesting feature of the plant. The mill-pulp is elevated by Morris pumps to a set of 12 conical classifiers, fitted with diaphragm plates near the outlet to prevent the formation of sand channels. These provide an overflow running off to the slime plant and an underflow, delivered to another set of eight diaphragm cones, which yield a further contribution to the slime plant. The underflow product of these last cones is delivered to a new type of rotary filter table, introduced by Mr. Caldecott, which removes practically all remaining slime and water, and yields a good leaching product of sand. Though unable at present to give details of this innovation, it may be stated that it comprises a table 20 ft. diam., with an outside filter ring 30 in. wide. The filtering medium is the usual cocoanut matting, upon which, however, a permanent bed of sand, $1\frac{1}{2}$ in. deep, is left by the inclined scraper-blade which turns the dewatered sand (60% of the mill-pulp) into the launder delivering to the pumps. Below the table there are six radial pipes applying a 3-in. vacuum, which draw off the slime and water. The tables (two are in use, easily serving the mill of 65,000 tons capacity) are rotated at 3 revolutions per minute, and have a normal working capacity of about 1000 tons of dry sand per diem. The sand product from the tables is washed down the launders with a 0.3% cyanide solution, and by the time it reaches the collector yats (which are also served by vacuum air-pumps, to facilitate the later stages of leaching), 50% of the gold is dissolved. From the collectors the sand is transferred by belt conveyors to the secondary treatment vats. Owing to the early introduction of the cyanide solution and the agitation the sand undergoes in its association, time of treatment is greatly reduced. Before the mill-pulp is delivered to the first set of cone-classifiers, the concentrate or tube-mill product has been eliminated by means of spitz-boxes and ordinary conical dewaterers. This scheme has been improved upon at the neighboring Simmer & Jack mine, where the heavy sand for the tube-mills is separated out in a single operation. Large conical classifiers with the diaphragm to ensure a steady thick underflow are here employed with great success.

The Transvaal's output of minerals and metals other than gold, coal, and diamonds reached a record height in April at the small total value of £36,356. The lesser industries are indeed developing slowly. This total is made up of the following principal items: tin ore, 257 tons,

valued at £21,228; copper ore, 165 tons, at £4345; and galena, 162 tons, at £1594. The remainder consists of lime, flint, magnesite, asbestos, graphite, and blende.

The schemes on foot for the establishment of large central electric-power stations have prompted the Government to appoint a commission to enquire into the probable influence of such power-supply companies on (a) the Rand gold industry, (b) the coal industry, (c) the Central South African Railways—which are under Government administration, (d) agriculture and irrigation, (e) any other industries or trades, (f) the employment of labor, and (g) the country generally. It is also proposed to ascertain what facilities should be conferred upon the companies of the State, what restrictions should be imposed upon them, and what powers of expropriation should be reserved. The evidence already given has been of great interest. Hans Behr made out a strong case in favor of electric power for all departments of mine-work, on account of the economy in capital and running costs, and the greater flexibility of the system. There are already two central generating stations on the Rand, at Brakpan and Simmerpan, and Mr. Behr advocated the erection of two new plants, one on the Rand and the other at Vereeniging, near great coal and water supplies. Mr. Spengler, chief engineer for the Vic-

Sand Filter Table at Simmer Deep.

toria Falls Power Co., presented remarkable figures in support of the view that the coal consumption in the future will nevertheless increase, owing to greater activity on the Rand. He estimates that about 27,000,000 tons of ore will be the Rand's annual crushing capacity in 1911, and judging by present arrangements for the partial or complete electrification of certain mines, the coal consumption will be 2,430,000 tons or 305,000 tons in excess of the figure for 1908. It may be mentioned that while the present cost of purchased power is 1.50c. per kw.-hr., it will eventually be reduced to 1.05 cents.

Although the Commission of Enquiry has only now commenced its investigations and is still far from issuing its verdict, the Het Volk or Boer party has already frantically expressed its opposition to the establishment of these central power stations. The scheme "would work havoc on the farming industry," "would endanger the prosperity of many districts," "would rob the owners of High Veld coal-farms," "would impoverish thousands for the sake of a few," "would throng the streets with unemployed," and it involved the granting of an "infamous concession." It is unfortunate that such expressions should be uttered before the facts have been made known. It is certain that central power stations will, or should, play an important part in the prosperous development of the Rand industry, and the Government now possesses a more direct and weighty interest in gold mining than hitherto, owing to the speedy utilization of water-rights and bewaarplaatsen (depositing sites) for which the mining rights are vested in the Crown. The demands of progress do not permit of the unnatural fostering of coal mines at the expense of the premier industry. The 'Backveld Dutchmen' are notoriously conservative in their ideas.

SALT LAKE, UTAH.

Boston Con. Mill. — Copper Output. — Grand Central Strike. — Ohio Copper. — International Smelter.

The Boston Consolidated mill has now been running at full capacity since the evening of July 3. The thirteenth and last section was completed several days ago. The mill has a normal capacity of 2700 tons, but A. J. Bettles says that they have demonstrated the practicability of treating more than 3000 tons in 24 hours. The saving averages close to 80%, which is the best performance of any of the Utah concentrating plants. With the Garfield mill of the Boston Consolidated running at full capacity, it is estimated that the company is making its copper at a cost approximating 9c. per pound. From this it is concluded that the total net monthly profit is about \$100,000. The company is the second largest copper producer in Utah, and in addition to the high recovery from its porphyry concentrate, its sulphide mine will soon be increasing its output. The total output of copper from Utah for the month of June is estimated at more than 10,000,000 pounds.

One of the most important pieces of work in the Tintic district during the year is reported by officials of the Grand Central mine. A prospect drift was driven 100 ft. to the west from the 2000-ft. level, and a fine body of copper and gold-bearing ore was opened. From the 1800-ft. another level has been started to the west to tap the same orebody. Later a third drift will be extended from the 2100-ft. level. It is believed that the new orebody is the Centennial-Eureka vein. If this be true, it will mean that the Grand Central has practically a new mine. It has already paid in dividends about \$1,500,000.

Colin McIntosh, general manager of the Ohio Copper Co., has been East. He says that the entire bond issue of the company has been sold, and that ample capital is at the disposal of the management. The first unit of the mill will be completed and commissioned within a few weeks. The remaining sections will be put in running order as quickly as the machinery can be installed. Arrangements for the smelting of concentrate have been made with the Garfield Smelting Co. This company will market its own product through the Heinze ore-selling agency in New York. The mine force is to be increased, and extensive development conducted on levels 3, 5, and 7. The Mascotte tunnel has been completed to the end-lines of the Utah Copper.

Structural steel is being delivered at the International Smelting plant in Pine canyon. Foundations for the machine-shops and power-house have been completed, and structural-iron workers are now engaged in erecting the steel. The railroad and steel manufacturers have agreed to deliver the material as fast as the smelting company needs it. Good progress has been made in the erection of the plant.

TERLINGUA, TEXAS.

Renewed Activity. — Gaines Lands. — Boquillas Mines at Marathon.

The quicksilver output of the cinnabar mines in the Terlingua district, situated about 90 miles south of Alpine, is being greatly increased by the renewal of development. The Texas Almaden mine, which is owned by Sanger Brothers, of Dallas, Texas, has entered upon a period of production after a shut-down of more than a year, due to the flooded condition of the lower workings. It is stated that the water is now under control and that the output of the mine promises to be very large. According to report, more than \$300,000 have already been expended in development upon this property. The Chisos Mining Co. is preparing to operate its mine upon a more extensive scale than ever before. This property has a record of bringing to its owners a net profit of about \$15,000 per month for several years. A 40-ton furnace was installed about a year ago. The workings extend to a depth of more than 400 ft., and the ore increases in richness with depth. The fact that the Terlingua district is 90 miles from the nearest railroad point and that the trip to the remote locality is full of discomforts has retarded the quicksilver development there very much. Another disadvantage is that every alternate section of land in

the district is owned by the State of Texas. In the absence of an adequate mining law there has been very little prospecting done upon these State lands, although many of them are believed to be rich in cinnabar ore, and probably other precious minerals. It is announced that William P. Gaines, of Austin, Texas, who controls about 128,000 acres situated in and close to the proved quicksilver district, has organized a strong company for the purpose of developing the minerals. Outcroppings of rich cinnabar ore have been found.

Americans have done some prospecting for cinnabar on the Mexican side of the Rio Grande, and it is stated that a number of promising claims have been opened, but the lack of transportation facilities has so far prevented much development work being done upon them. Marathon, a town situated 25 miles east of Alpine on the Southern Pacific railroad, is to be made a shipping point for the ores from the rich Boquillas mines which are owned by Carlos Moser. These mines are situated close to the Rio Grande, but across the river in Mexico, and are 100 miles from Marathon. Mr. Moser is now installing an aerial tram six miles long, to convey the ores across the river from the mines. From the end of the tram on the Texas side of the river the ore will be hauled to Marathon in wagons, drawn by traction engines. Mr. Moser has built a good wagon-road to connect the mines and Marathon. The mines are large producers of silver-lead and of zinc ore. More than 70,000 tons of ore are now upon the dump.

COBALT, ONTARIO.

Beaver Con. — Lawson. — Coniagas. — Silver Cliff. — South Lorrain.

The ore-shoot in which high-grade ore was first found on the Beaver Consolidated mine in South Coleman has recently become productive again. It was struck at 180 ft. from the main cross-cut; for 40 ft. it was barren, but at this point the ore occurs in a vein about 6 in. wide bearing 2000-oz. ore. The power-house, which was burnt down, is being re-built, and the compressor and plant should be running again by the middle of July. Ore is only found in this vicinity a hundred feet below the surface and all properties in the neighborhood are sinking. The Ophir has just put in a plant. It consists of a 100-hp. boiler, a 6-drill Sullivan compressor, and two pumps. For the John Black, a neighboring property, a small compressor and an 80-hp. boiler has been ordered. The Lawson property of the La Rose Consolidated group has struck another high-grade vein. It runs at right angles to the richest vein in the camp and was found as a mere stringer in a cross trench. At the bottom of a small test pit it is 18 in. wide, and shows little but smaltite and silver. Two assays gave just short of 1000 oz. per ton. The company is getting air from another of its properties, the University, but foundations are being laid for a boiler and ore-houses. The Coniagas mill will be enlarged to double its present capacity. The mill now treats 80 tons per day and there are 30 stamps. Thirty more stamps and extra concentrating tables will be added, so that 160 tons can be milled per day. It is expected that the enlargement will cost \$40,000 and will be completed in four months. The output of the mine will then be six cars of high-grade ore per month.

Pittsburg capitalists interested in the Carnegie Steel Co. have bought the Silver Cliff property on Cross lake for \$75,000. W. H. Jeffery, who negotiated the deal, is general manager and is pushing development. There are many rich narrow veins and the country rock for several feet shows silver leaf. The two producing mines of the South Lorrain camp on Lake Temiskaming have recently installed plants. The Wettlaufer, a Buffalo company, now has running an Ingersoll-Sergeant compressor of 5-drill capacity, driven by two 60-hp. boilers. They have one car of high-grade ore and two cars of low ready to ship. The ore taken from the 65-ft. shaft will pay for the whole plant. The Keeley has in place two Crossley gas engines, one of 150 hp., and the other of 65. A 40-kw. generator will run the hoists, the pumps, and supply the light for the camp. A Canadian Rand air-compressor will supply power to run the drills. All the plant, with the exception of the compressor, was imported from England.

GOLDFIELD, NEVADA.

Consolidated Reduces Earnings.—Diamondfield Discoveries.—Western Smelters Plant at Carson City.

An official statement has been made by A. H. Howe, secretary and treasurer of the Goldfield Consolidated, embodying estimates of the gold production in June and explaining a change in the policy of the company. While the new policy will lessen monthly net earnings, it will, through the mining of ore of the lowest profitable grade concurrently with the high and medium grade, increase final profits. In outlining this policy Mr. Howe said: "All the ore in our stopes having a value sufficient to afford a profit in treatment will henceforth be stoped at the same time the higher grade ore is taken out, irrespective of the relation such values may have to any fixed and arbitrary basis of earnings. While this policy results in a considerable reduction in the value of the ore milled, and a consequent lessening of monthly revenues, it follows that its effect will be to save ore which would either be lost or which would later involve additional expense to produce. It is deemed wise to accomplish the production of this ore under an original rather than a secondary mining expense. That this policy will materially enlarge the productive capacity of the property and greatly lengthen its life must be apparent to the most casual observer. Continuous production such as we announce for June will serve to pay operating expenses, and at the same time maintain dividends at the established rate of 30c. per share quarterly, and we believe for a longer time than by leaving the low-grade ore for future production. Our estimated production for the month of June is as follows: Tons produced, 19,410; estimated net recovery, \$547,000; estimated total cost of production, \$150,000; estimated net profit, \$397,000. The relatively small tonnage was caused by a shortage of electric power, lasting for five days and due to the recent wash-out."

In spite of the heavy falling off in profits, there is nothing of a startling nature in this announcement, as the policy was outlined by the general manager before the 600-ton mill was completed. During the early months of operating this mill, and while the known orebodies were being opened on an extensive scale, it was necessary to mine and treat much ore of higher grade than that from which the best results in reduction are obtained. At no time has it been the intention to neglect the lower grade ore, nor has it been expected that the mills of the company would continue permanently to treat \$40 ore, as this would have entailed leaving in the workings a vast tonnage of low-grade. Shortage of power has kept the mills of the district idle for several days, but the July production of the Consolidated company will probably exceed that for June, although at present no high-grade ore is being shipped. The belief expressed in some quarters, that the new policy is due to a shortage of the better class of ore in the mines, is ridiculed by men acquainted with the workings. It is common knowledge that many headings are bulkheaded with heavy timbers to protect the high-grade ore.

Two recent ore discoveries in the neighborhood of Diamondfield, in the northeast portion of the Goldfield district, in and near the Golden Daisy lease, are attracting attention. Some rich samples have been secured in the old Detch-Brewer workings, which are being operated by Bruce Jones and Guy Millard. A short distance north of the Daisy an ore-shoot has been opened at a depth of 65 ft. on the Goldfield Belmont and on the extension of what is known as the Graham vein.

Owing to the decision rendered some months ago requiring company meetings of Arizona corporations to be held in that Territory, many Nevada companies are re-incorporating in this State. Among these is the Western Smelters Corporation. The president, J. A. Yerington, of Carson City, is now at Phoenix, Arizona, seeking dissolution of the concern for the purpose above stated. This company is building a 250-ton copper smelter about five miles east of Carson City. The plant will be in operation by the end of this year. The ores available from the company's mines carry such a large excess of iron that a local market will be created for the silicious Goldfield ores.

BRITISH COLUMBIA.

Rossland Mines.—New Dominion Copper.—Coal Mines Resume.—Salmo District.—Highland Valley.—Mineral Output.

The strike made some days ago on the Blue Bird property in the South Belt at Rossland has developed better than was at first anticipated. The lessees have taken out about 30 tons of galena ore which is expected to yield \$80 per ton. Three shifts of miners will be put at work. The company will take the property over as soon as the present lease expires. The shaft on the Hattie Brown, in the South Belt, has reached a depth of 70 ft., the vein at this point assaying about \$49 and being 6 ft. in width. Cross-cutting on the surface of this property is giving very good results. A meeting of the board of directors of the B. C. Mining & Development Syndicate was held during the past week, G. A. Ullerick, president of the company, being present. Work at the Le Roi No. 2, Ltd., goes on as usual with good results, and the confirmed reports of the operations for May show that 2168 tons of first-class ore was shipped, for which the smelter receipts amounted to \$48,549, a fraction over \$22 per ton, which is the average value of the first-class ore shipped by this property. Eighty-two tons of concentrate was also sent to the Trall smelter, from which the returns were \$41.44 per ton. The fixed charges at the Le Roi No. 2, Ltd., are not very heavy, as they maintain no large power-plant.

Among the newly registered mining companies in this Province appears the name of the New Dominion Copper Co., capital \$1,000,000, in shares of \$5 each; also the Argo Mining & Tunnel Co., capital \$125,000, in 25c. shares. The first indicates that the work of getting the affairs of the New Dominion Copper Co. in form is going forward. The Argo Mining Co. is driving an adit into the hill at Greenwood, some distance south of the adit of the Phoenix-Greenwood property. The tunnel on the E. P. U. claim, near Greenwood, is now in about 1300 ft., being the result of work done by a local syndicate during the past couple of years. According to the calculations of the operators, the vein should be reached at an early date.

J. S. Airheart, of New York, is in Nelson, arranging for the resumption of work at the Highland mine and mill, which H. N. Roach & Co., with whom he is associated, recently acquired.

The mining situation in this district will be much relieved by the action of the coal miners in Southern Alberta in signing the Macleod agreement, thus settling all labor trouble in the coal fields. Work will be resumed at many of the mines immediately. The resumption at Coleman will give a supply of coke to the British Columbia Copper Co. which will start up its mines and smelter as soon as the fuel bins are full. A big body of ore was opened up in the St. Eugene mine, Moyle, last week. This property, which is controlled by the Consolidated Co., shipped 807 tons of high-grade product to its smelter at Trall during the week ending June 26. A new adit has been started on the Aurora property, across the lake from the St. Eugene. This will be 150 ft. above the lake and the same distance below the main level. Mining affairs are particularly lively in the Salmo district this season. A new strike has been made on the Clyde group of five claims, the vein on the surface showing the same characteristics as the Queen, Mother Lode, and other prominent adjacent properties.

A vein nearly 300 ft. wide, that carries \$26 to \$258 per ton in gold, has been found near Lillooet lake. The find was made by an Indian, and many locations have been made in the neighborhood. There is active development in Highland Valley district. Work is now going on at the Twenty-Four, Ball group, Topnotch, Tamarac, I. X. L., and other claims. Several deals are pending with New York and Butte capitalists. The mineral product of this Province for the year 1908 is valued at \$23,851,277, according to the figures of the Provincial Minister of Mines, whose report is just off the press. This was somewhat under the figures for 1907, although the tonnage was greater by 279,492 tons. The Boundary-Phoenix and Rossland districts maintain their positions of prominence, having accounted for 71.6 and 14.5% of the total output, respectively. The total tonnage mined, exclusive of coal, was 2,083,606 tons.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Selenium is recovered from the slime resulting from electrolytic copper refining. It sells for approximately \$2 per pound.

Manganese steel may easily be 'burned', and thus lose its valuable properties, if heated for quenching above 1000° C. Such heating is also liable to develop deep cracks in the metal.

Copper ore at the United Verde mine, in Arizona, does not exist in a vein of great longitudinal extent. It is described as being essentially a 'pipe', or ore-shoot, approximately 200 by 2000 ft. in horizontal section, but persistent in depth.

Slate, according to ordinary usage, denotes a rock which has more or less perfect cleavage, adapting it to various commercial uses, and in which the constituent particles, with few exceptions, can not be distinguished except in thin sections under the microscope.

Metal prices vary with many conditions. The 'normal price' is the average price over a long term of years. The 'basic price' is that which marks insufficient production and the turning point toward a rise. Both must be considered in estimating future prices.

Exhaustion at some depth is the fate of all mines. Of several hundred dividend-paying metal mines studied, not 6%, outside the Rand, yielded profits from ore won at more than 2000 ft. in depth. Not 20% yielded profits below 1500, and a majority paid their dividends from ore won at depths of less than 500 feet.

Lignite in the Magellan archipelago, in Chile, occurs in rocks of Tertiary age, which are a continuation of the deposits found in the Argentine pampas. The crystalline rocks of these islands consist chiefly of granite and mica schists; the eruptives consist chiefly of trachytes, with more recent gabbros and dolerites.

Pacing may be done easily and with an average error not exceeding 2% on level ground and 10 on the roughest. In pacing it is well to use a step slightly longer than ordinary. With most men 1000 to 1100 double paces may be counted a mile, but each should accurately determine his own pace by repeated trial before beginning work.

Hammers for geological work should weigh one to one and a quarter pounds, without the handle. Chisel points are to be preferred for work on soft rocks where digging must be done, as on a coal outcrop. Only the best steel should be used, tempered so it will not chip. Trimming hammers for museum work are best square-faced, and should weigh about six ounces.

For desert travel horses should be picked, where possible, which are used to the work, as others fret on sandy roads and rapidly weaken from drinking

saline water. They are also in danger from pneumonia from the cold of winter nights and the wide extremes of temperature. During winter journeys blankets should be provided to protect the animals at night.

Copper subjected to mechanical strain may be restored to its former ductility by annealing. Hard copper, which can be extended only 45 to 53% of its length, may by annealing have its ductility so increased as to admit of an extension of 120%. Heating copper to a bright red for any considerable time also destroys its ductility, which, however, can also be restored by annealing.

Briquetted or 'agglomerated' fuel is made by pressing in molds a mixture of coal dust and small sized pieces of coal or other carbonaceous material, together with a binding substance. The most common binder at present commercially available is a pitch, made either from coal tar or water-gas tar, but other substances, such as starch, lime, and sulphate liquor, have been used. The mixture of coal and binder is heated and subjected to heavy pressure in molds.

Pitch is the angle made by an ore-shoot in the plane of a vein, and is measured from the horizontal. This term should be held distinct from dip, which is the angle of the axis of inclination of a vein or stratum measured from the horizontal. Thus a vein may have a dip only; an ore-shoot in a vein will participate in the dip of the vein and possess its own angle of pitch. Striae, scorings, or slickensides in a vein, as well as rift, may have an inclination different from the dip; to this the term pitch may be applied.

Secondary impoverishment is the humorous antithesis to secondary enrichment of veins, proposed by Henry Hobart Knox. He cites deposits near Ekaterinburg, in the Ural mountains, Russia, where a gossan is followed by a barite zone, succeeded by an auriferous pyrite zone, which in turn is underlaid by a cupriferous pyrite zone. This is a normal succession, the leaching here observed being particularly characteristic of veins in the arid regions of the western United States. In the case described by Mr. Knox, removal of the sulphides by leaching caused squeezing of the vein by the pressure of the hanging wall so that it had been reduced to less than one-third its normal size as revealed lower down.

Smokeless combustion is possible with many types of furnace. The stoker and the furnace must be so built that combustion will be complete before the gases strike the heating-surface of the boiler. When partly burned gases at furnace temperatures near 2500° F. strike the tubes of a boiler that are perhaps at 350° F., combustion is necessarily hindered, and may be entirely arrested. The length of time required for the gases to pass from the coal to the heating surface probably averages less than a second, and the gases must be intimately mixed to insure complete combustion. Mechanical stokers are to be preferred, for the reason that the regularity of their feed tends to insure uniform distillation of gas and avoids its sudden generation in large volume that the air present is insufficient to consume.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Protection of Investors.

The Editor:

Sir—In a letter concerning the 'Protection of Investors', in which F. J. H. Merrill calls special attention to the need for the protection of those who invest in prospects, I find myself obliged to disagree, either with his statement as to the mortality among prospects, or to change my idea as to the proper definition of the word 'prospect'. Mr. Merrill states that "The mortality among prospects is probably no greater than among children, and failures in mining are no greater than in ordinary business pursuits, where only 2% achieve success." The old English mortality tables compiled by Farr show that 30% of all male children die under the age of five. Beyond this age the mortality of children is low, rather less than 1% per year. The American tables give slightly lower results, and within the past 15 years increasing knowledge and care have further decreased the figures. Undoubtedly far more than 50% of the children born reach the age of 21. Now, if my idea as to what constitutes a prospect is correct, nothing like this percentage ever become successful mines. I believe the old-time prospector would consider the same showing worthy of the name 'prospect' which the Utah judge ruled as constituting a valid location. The ruling is that "A valid location of a mining claim may be made whenever the prospector has discovered indications of mineral." Possibly this is an extreme view, but it appears to be borne out by the Century Dictionary, which defines a prospect as: "In mining, any appearance, especially a surface appearance, which seems to indicate a chance for successful mining." If we accept these definitions, which do not appear to even require that a pick shall have been stuck into the ground, the number of prospects which fail to become mines drifts off toward infinity. If, however, we consider as 'prospects' only those openings in the ground actually showing quartz or other rocks and minerals which commonly contain valuable metals, I still believe the number of prospects which become paying mines will fall far below the 2% referred to. Gifford Pinchot considers that a prospect ceases to be such when it begins to produce. In his letter to the Forestry Committee of the Mining Congress, published in the MINING AND SCIENTIFIC PRESS for May 29, 1909, he says that men should have free use of timber from the forests on any claim, "so long as it is a prospect and not a producing mine. When a prospect becomes a mine and begins to produce ore, it is then a commercial enterprise." This distinction will not, however, serve in considering the protection of investors, since a mine producing, or shipping, ore is not necessarily a paying mine. To be a producer, from the standpoint of the investor, it must pay a dividend. Unless it returns the capital invested, with reasonable interest,

it is not a paying mine. But one need only look at the thousands of prospects within ten miles of Cripple Creek or Goldfield, or visit Greenwater, to feel confident that far less than 1% of the prospects become paying mines. In 1892 I was told that there were over 1200 claims located in the New World Mining District, in Montana. Most of these were probably worthy of the name of 'prospect'. I doubt if one of them has become a paying mine, as above defined, though the advent of a railroad might change many of them into producers. There are many other portions of the country where similar conditions exist. On the contrary, there are districts with a relatively large proportion of paying mines. Anaconda Hill, Bingham, or Gilpin county, are examples. Yet these are surrounded with zones of non-productive holes, some with promising indications.

The terms 'prospect', 'mine', 'producing mine', and 'paying mine' are, like many others in common use, not easy of accurate definition. But I can conceive of no acceptable definition of the word 'prospect' which would admit of the statement that "the mortality among prospects is no greater than among children." And it is such statements as these, made by reputable professional men, that the promoter seizes with avidity for the adornment of the prospectus which catches the identical class of investors that Mr. Merrill wishes to protect.

GEO. A. PACKARD.

Boston, June 15.

Legislation Regarding Oil Lands.

The Editor:

Sir—Having carefully studied the bill introduced in the House at Washington by S. C. Smith of California, "To provide for the disposal of lands chiefly valuable for oil and asphaltum," I should like, in the interest of the oil industry of California, to offer some remarks on the subject. The main object of this bill is to repeal the Act of 1897, whereby the entry and patenting of land containing petroleum and other mineral oils was placed under the placer mining laws of the United States. This object will undoubtedly meet with general approval; I do not think that anyone interested in the legitimate development of the oil industry desires to have this regulation kept on the statutes any longer than can be helped. There are, however, some clauses in the bill offered by Mr. Smith which, it appears to me, will tend to prevent legitimate development of such lands as are only of prospective value. It is provided in this Act (Sec. 2) that no claim exceeding 160 acres can be claimed by one person, and besides that, such claimant is not entitled to such a claim if he has previously claimed any land in the same county under the provisions of this Act. I consider this clause unjust to the oil industry. The drilling of a well in an undeveloped country is a hazardous and a costly undertaking. It may cost all the way from \$20,000 to \$60,000, with no assurance that the ultimate result will repay the investment. To prevent a person who has spent his money in such an undertaking from getting more than 160 acres, in case his efforts are crowned with success, appears to me to be unjust. The result of his investment will make the land di-

rectly contiguous to that on which he has spent his money, just as valuable as his own claim, and it appears to me only just that he should have a preference in realizing that increment of value. In case, however, that his efforts prove fruitless, it seems to me rank injustice that he should be prohibited from trying again in the same county in which his first attempt was made. Why a man should be restricted in his rights because he has spent his time and money in trying to develop the public lands of the United States is to me incomprehensible. In Sec. 3 it is stated, "No individual or corporation shall be a party to final proof proceedings under this Act on more than one claim." I am satisfied that this clause will seriously interfere with the expansion of the oil field. I realize the general trend of public opinion against large holdings of property, but in this case it must be considered that the development of oil land demands capital, and it will certainly not take hold of any such a risky undertaking as drilling for oil in an undeveloped country when its chances of remuneration, in case of success, are so restricted. In describing the conditions under which patents may be obtained for an oil claim, should a discovery be made, the following clause is used, "That there has been made such drillings or excavations, on said claim as enables the claimant to produce oil or asphaltum, or both, in commercial quantities." This clause, in my opinion, will give rise to considerable controversy. If I understand the term "commercial quantities" correctly, it means quantities which can be operated with a profit. A well producing 25 bbl. of high-grade oil, situated close to transportation, may be operated at a profit, while a well situated at a great distance from transportation may be valueless even if it produces 100 bbl. of oil per day. The injustice of this clause is flagrant; the man who risks his money in developing territory ahead of the times would be prevented from getting a patent. It seems to me more just to follow the policy used by the Southern Pacific Railroad Co. in giving leases on its land, namely, to stipulate a certain production. Sec. 3 further reads: ". . . if there are any veins or lodes of quartz or other rock in place, bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits known to exist at date of filing such application for patent, title thereto shall not pass under any application, entry, or patent under the provisions of this Act, but are hereby expressly declared to be reserved therefrom, and such vein or lode shall be subject to location and entry by any qualified person or persons under the provisions of the existing United States Mining Laws applicable thereto: Provided, however, that any declarant who discovers any vein or lode bearing asphaltum, gilsonite, elaterite, or other like substances within the limits of the land included in his declaration or entry under this Act shall have the preferential right for a period of 90 days after the discovery of said vein or lode within which to locate same, under the provisions of the general mining laws . . ." It must be noted that no mention is made in this clause of gypsum, the mineral most commonly found in the California oil fields. According to Sec. 2329, Revised Statutes, gypsum may be located as a placer claim, and consequently falls under

the head of "other valuable deposits" mentioned in the above quotation. Is the meaning of this section, that the same land can be covered by an entry for oil and asphaltum under this Act, and simultaneously by a placer claim for gypsum? While this conclusion is apparently an absurdity, yet I do not see how this clause can be otherwise construed.

While I have criticised some clauses in this bill, I am fully convinced that the main object of the bill is correct. I trust that my criticism may open a discussion whereby some improvements may be caused to be made in this bill, which may render it still more beneficial to the oil industry of California.

The First Rock-Drill.

The Editor:

Sir—Perhaps no piece of machinery has accomplished as much for the world at large, and the mining profession in particular, as the rock-drill, and it seems to me not only right, but important, that we give full credit for its invention and perfection to the man—a brother engineer—to whom it is really due. Recently there appeared in your columns the following: "The first practical rock-drill for hard rock, a pneumatic percussive drill, was designed, not for mining, but for tunneling purposes, by Sommeiller, for the Mont Cenis tunnel; priority of conception seems to belong to an American, Fowle, who patented such a drill in 1851, and an Englishman, Bartlett, in 1855; but the Sommeiller machine, designed in 1857, was the first to be actually used, in 1861; it seems to have been first applied to mining at Moresnet, in Belgium, in 1863." Similar sketches have also appeared elsewhere. I believe them to be incorrect, and that we are doing an injustice to the memory of that great American engineer, General Herman H. Haupt, when we allow them to pass unquestioned.

While yet a lad, pondering upon the fascinations of an engineering life, I was fortunate in being thrown into close contact with General Haupt for a brief space of time; the memory of the charm of his home life, the kindness of his nature, and the rectitude of his spirit, remain with me vividly to this day. It was during this time that I first heard of his work at the Hoosac tunnel, and how the remarkable speed while the tunneling was under his direction had been accomplished by his invention and perfection of the rock-drill; and I recall being told that, after Governor Andrew had wrongfully succeeded in wresting the work from him, he was given a banquet by an engineering society in England as a recognition of his work in tunneling and in the invention of the rock-drill.

This is a boy's recollection of twenty years ago. Let us see if it can be verified. In 'Reminiscences of General Herman Haupt', written by himself, appears on page 28, among 'notes and a personal sketch by Frank A. Flower', the following: "At the time of the suspension of tunnel work in 1861, Mr. Haupt had made great progress in rock-drilling machinery, and had developed a machine that was far in advance of the perforator at work in the Mont Cenis tunnel at the same time. This drill was improved by a Mr.

Taylor, in the employ of J. A. McKean, who represented Mr. Haupt in Europe and accomplished more rapid progress, at less expense for repair, than any drill used in the St. Gothard tunnel or elsewhere in the Old World; but Haupt never received any royalties or other compensation for its use. Mr. Haupt's knowledge of engineering principles, his great energy and experience, his genius for inventing more efficient rock-drilling and other machinery, and his tact and economy in the management of men . . . would have resulted in completing the tunnel without a cent of cost to the State;" and on the same page is the following: "For some years subsequent to the war, General Haupt followed his profession of consulting engineer in Pennsylvania. In 1867 he visited Europe, upon invitation of the Royal Polytechnic Society of Cornwall, to explain his system of mining and tunneling by power machinery. One of the rock-drills invented by him for use in the Hoosac tunnel, and which was the type of those used in driving through the great St. Gothard tunnel with so much rapidity, was on exhibition and received the highest honors awarded by the society."

The Hoosac tunnel was begun by Mr. Haupt in 1856, and his work there was continuous until 1862. My recollection is that Mr. Haupt perfected his drill one year after beginning work, which would make it in 1857, and give it priority of practical usage, and I believe the claim can be established that he also had priority of conception, although he never, to my knowledge, patented his device. It seems quite certain that, although the Mont Cenis tunnel was completed in 1870, and the St. Gothard not begun until 1872, it was the Haupt form of drill that was the most effective in the latter tunnel, and neither the Sommeiller nor the Mont Cenis form. What the especial characteristics of the several forms of drill were I have no way of knowing, but it would be interesting to have a sketch of them from those who are conversant with the original drills.

Wheeling, West Virginia, June 10.

Vein-Continuity on Mining Claims.

The Editor:

Sir—An erroneous impression having gone abroad that the Land Office required proof of continuity of a vein along the entire length of a claim before patent would issue, I beg to submit a copy of the following circular letter from the Interior Department on the subject:

Registers and Receivers,

U. S. Land Offices.

Sirs: The attention of the Department has been called to the last clause of paragraph 41 of the mining regulations, approved March 29, 1909, which provides as follows: "The vein or lode must be fully described, the description to include a statement as to the kind and character of mineral, the extent thereof, whether ore has been extracted and of what amount and value, and such other facts as will support the applicants' allegation that the claim contains a valuable mineral deposit."

It seems that the expression, "the extent thereof," is being construed as meaning that the applicant

must affirmatively show by proof of exploration that the vein exists in fact throughout the whole length of the claim. This construction of the paragraph is erroneous. By the words quoted it was intended to require the claimant to show the existence of a vein in such workings as he relied on to establish a discovery. By the extent of the vein was meant its size and quality as disclosed. That being done, the presumption exists that the vein extends on its strike throughout the whole length of the claim as located. The sole purpose of that part of paragraph 41 quoted was to enable the Land Department to know, so far as applicant can reasonably show, the definite facts upon which the right to the patent is predicated, so as to determine whether a valuable mineral deposit exists in the land claimed. You will give this as wide publicity as possible, furnishing it to such newspapers in your district as may want to publish it or refer to it as a matter of news.

FRED DENNETT.

Approved June 11, 1909.

Commissioner.

R. A. BALLINGER, Secretary.

I hope this will carry comfort to many who may have been disturbed by the dissemination of a wrong understanding of the order.

San Francisco, June 20.

Cornish Pumps.

The Editor:

Sir—The statements which have appeared in the MINING AND SCIENTIFIC PRESS lately in regard to the superiority of the Cornish pump over direct-acting pumps should not pass without having some light thrown on the other side of the question. In the article in the February 20, '09, issue, by H. F. Collins, their good points are enumerated as: (1) reliability, (2) flexibility, (3) durability, (4) adaptability to sinking. The latter point is well taken, but the three former ones are simply a matter of first cost. If the mine owner should spend half as much money on a direct-acting pump as a Cornish pump would cost, he would be liable to get just as good service out of it.

Mr. Collins says that a Cornish pump which ordinarily runs 1 to 1½ strokes per minute can easily be speeded up to 7 to 8 strokes per minute. This is equivalent to saying that if a pump is required to pump 1000 gal. per minute, one that is capable of pumping 8000 gal. is installed. If this same policy were followed in selecting a direct-acting pump, its life would likewise be prolonged eight times, or, say, to 80 years, repairs would be few and far between, and the rest of the superintendent at night would be just as sweet as if he had a Cornish pump under his charge. The direct-acting pump will be just as reliable, flexible, and durable, and at a much smaller first cost. Anybody that has an insight in the manner in which pumping engines are purchased will, however, understand that a manufacturer who offers a pump at a price five times that of other builders stands no chance of selling his pump, no matter how well he may argue the three good points mentioned.

F. F. NICKEL.

Hazleton, Pennsylvania, June 22.

HISTORICAL GEOLOGY OF CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

(Continued From Page 392, June 26.)

Tertiary (Cenozoic).

Coast Ranges and Great Valley. There has been much controversy regarding the stratigraphic relation of the Eocene Tejón and the Cretaceous. Apparently the stratigraphic continuity of the Tejón and the Chico is well established, and the non-conformity observed in several places is due to the contact with Lower Cretaceous strata.⁵⁷ The lower member of the Eocene, in Contra Costa county, is called the Martinez, and consists of a thick accumulation of sandstone. In central California the Eocene is represented by the Tejón, usually an extremely light-colored sandstone, often containing concretions, with subordinate shale and some limestone lenses. It constitutes the coal-bearing horizon of central California.⁵⁸ The Eocene is sparingly represented on the coast north of Ventura county, but well developed along the western and southern edges of the San Joaquin valley, and extends along Ventura county toward the ocean, until it is finally buried under more recent deposits. This seems to indicate that during the Eocene the Great Valley formed an arm of the ocean, with an outlet at the southern end.⁵⁹ In the San Rafael range, Santa Maria district, is a great series of dark-colored shales, alternating with massively bedded sandstone, which has not been differentiated. Probably Knoxville strata occur at the base; the higher strata represent the Upper Cretaceous or the Eocene, or both, while it may include at the top, part of the Lower Miocene. The Santa Ynez range is mostly composed of a terrane equivalent to all of the Tejón and the Lower Miocene. The Eocene and Lower Miocene beds are conformable. In southern Santa Barbara county, the Eocene is represented by the Topatopa formation, and the conformably overlying Sespe formation, which may be partly Oligocene, which in turn is overlaid conformably by the Lower Miocene Vaqueros.⁶⁰ (See also below, Southern California). On the coast north of Santa Barbara county, a probable Eocene series is reported at Carmelo bay, Monterey county, which appears to be identical with the coal-bearing sandstones of Malparo canyon, about two miles distant, which are believed to be of Tejón age. This series of sandstones and conglomerates, with some argillaceous shales, is named the Carmelo series.⁶¹ Some sandstone beds near Pillaritos, on the peninsula of San Francisco, are also probably of Tejón age.⁶²

Along the southwestern edge of the San Joaquin

valley the Eocene forms several belts swinging northward in a broad curve around the outer flanks of the San Benito mountains. The lower member consists of concretionary sandstone, usually with conglomerates at the base, the Avenal sandstone; the middle member consists of brown, bituminous, or carbonaceous shale, with sands and clays, the Kreyenhagen shales. The coal mines near Coalinga are in these shales; the upper member is better developed north of Coalinga, and consists of but slightly consolidated sands, the Domijean sands.⁶³ In the vicinity of Coalinga the Eocene is oil-bearing, probably the shale middle-member.^{63 64} There is no general unconformity between the Eocene and the Miocene, suggesting that no profound disturbances occurred at, or near, the close of the Eocene. In many places, however, the Eocene was greatly eroded before the deposition of the Miocene.⁶⁵ This relation suggests that the differential oscillations, and intervening periods of quiescence, worked out in detail for the Klamath region and the Coast range in northern California in Bulletin 196, U. S. Geol. Survey, holds good, at least to a certain extent, for the entire California Coast region.

The Oligocene is, as yet, only recognized in one locality in California; on the San Lorenzo river, Santa Cruz county. It is called the San Lorenzo formation.⁶⁶ The Miocene is subdivided into four subdivisions: the Vaqueros or Temblor (Lower), the Monterey, the Contra Costa Miocene, and the San Pablo (Upper). The Vaqueros, also called the Temblor, or the Agasoma zone, consists prominently of sandstone, and represents the Lower Miocene shore-deposits, while the Monterey shales are deep-water sediments, indicating a gradual subsidence during the early and Middle Miocene.⁶⁷ The fauna of the Lower Miocene differs to some extent in the Coast region from that in the great valley. It would therefore appear that the sea had not reached as far east in the earliest Miocene as it did later, and that the thick shale-beds, overlying the lower sands in the Coast region, were formed while sandy beds were deposited to the east.⁶⁸ On the coast the Vaqueros contains, near the base, considerable conglomerate; and in San Luis Obispo county, and at Point Sal, beds of volcanic ash are intercalated, indicating volcanic activity during the period of their deposition.⁶⁹ This occurrence must, however, be considered local, as east of the Santa Lucia range no volcanic ashes are found in the Vaqueros. The Temblor beds, on the east slope of the Mount Diablo range, consist of sandstone and shale.⁷⁰ On the coast of Santa Barbara

county the Vaqueros lies conformably upon the Eocene, and in the Santa Ynez range the Vaqueros and the Eocene are so closely related that they cannot be differentiated.⁷¹ The Monterey shales, or bituminous shales, consist of a thick series of more or less silicious, organic, deep-water sediments, forming partly white, soft, porous, and chalk-like shales, partly dense, compact, light-gray, regularly banded flinty layers. These shales are generally bituminous. At many places the shales are inter-stratified with sandy beds, suggesting that during their deposition deep-water and shallow-water conditions oscillated.⁷² This formation is widely distributed through the Coast region, south of the bay of San Francisco, bordering the coast at many points, and forming a conspicuous, although not continuous, terrace along the river valleys and the west rim of the San Joaquin valley, that generally rests conformably on the Vaqueros sands. Occasionally the latter are absent, and the shales rest unconformably upon Cretaceous or Franciscan rocks. In the vicinity of the bay of San Francisco the Monterey shales consist of thin beds of dark, flinty chert, weathering white, alternating with thin bands of dark-brown shale, of a bituminous character, with numerous beds of whitish, fine-grained sandstone and lenses of limestone. The significance of the above rhythm of sedimentation, similar to that of the Franciscan radiolarian chert, is not clear.⁷³

Further south along the coast, the Monterey consists of white or light-yellowish, shaly strata, generally soft and chalky, of a porous character, due to hollow molds of minute organisms, and beds of a compact, light-gray, and opal-like flinty rock. At Point Sal the basal portion of the bituminous Monterey is a stratum of gypsiferous clays, overlying a sandstone, probably equivalent to the Vaqueros.⁷⁴ Although some volcanic material is probably present in the Monterey shales, their main character is that of organic deep-water deposition. These Miocene shales probably form the principal horizon from which most of the oil in California is derived.⁷⁵ In many portions of the southern Coast Range region the Monterey is distinguished by its diatomaceous character. The highest grade of diatomaceous earth is found in San Miguelito canyon, south of Lompoc. This diatomaceous earth belongs to the upper division of the Monterey shales.⁷⁶ At many places the Monterey oil-bearing shale has been altered, through combustion of the hydrocarbon content, into a pink or deep brick-red shale, or into a hard, vesicular rock-like scoriaceous lava.⁷⁷ After the deposition of the

Monterey shales, an uplift must have taken place, raising the entire region of western California above deep-sea conditions, partly above sea-level into the zone of erosion.⁷⁸ Whether the Contra Costa Miocene, which is only found in the vicinity of Mount Diablo, is the remnant of a Monterey shore-deposit, or of a post-Monterey deposit, is apparently still an open question. The Upper Miocene, San Pablo formation, consists chiefly of sandstones, with considerable tuff, especially in the upper portion. The San Pablo generally rests unconformably upon the underlying Miocene strata, although in some localities this unconformity is hard to trace.⁷⁹ The post-Monterey uplift must have brought part of the Coast region above sea-level, for in places the San Pablo is missing. In the northern Coast Range, at Point George and at Crescent City, the Upper Miocene is represented by the Empire beds; and northeast of Crescent City by the Wymer beds, soft, iron-stained, slightly indurated shaly sands. The lower portion of the Wildcat series at Rio Dell on Eel river, near Ferndale, is also probably Upper Miocene. Southwest of Covelo, Mendocino county, on Middle Fork at the mouth of Salt creek, is a probable Miocene deposit containing a bed of coal.⁸⁰

In San Luis Obispo county, there is a difference between the San Pablo east of the range (the Santa Margarita beds), and the San Pablo west of the range (the Pismo beds). In the upper Salinas river, and in San Luis Obispo county, the San Pablo contains diatomaceous beds.⁸¹ The Ione formation is its correlative in the Sierra region. In Tulare county the Ocaya creek beds are probably its correlative.⁸² Near Coalinga the San Pablo is represented by the Coalinga beds, which, however, may be the equivalent of the Contra Costa Miocene, and by the Etchegoin beds, consisting of bluish sands or gravels, overlaid by the San Joaquin clays, presenting a banded appearance due to the difference in color. The Coalinga beds are named the Jacalitos formations by the U. S. Geological Survey.⁸³ In the Berkeley hills the Orindan and the Trampan formations are the equivalents of the upper San Pablo. The tuffs of the latter are found at the base of the fresh-water Orindan, and the fauna of the overlying Trampan is closely allied to that of the San Pablo.⁸⁴ Along the coast in Santa Barbara, Ventura, and Los Angeles counties, the Miocene strata above the Monterey shales are not differentiated from the Pliocene Fernando formation, which includes probably some of the Upper Miocene. In the Summerland district it rests unconformably upon the Monterey, but in the Santa Ynez range this unconformity is slight, and the break between the two

formations is mainly indicated by the change in character of the deposits from organic, probably deep-water sediments, to sandy and gravelly deposits derived from erosion.⁸⁵ There is no doubt that the Upper Miocene represented a period of volcanic activity, synchronous with that in the Sierra region. During this period occurred the post-Miocene uplift of the Coast range, which was followed by the post-Miocene interval of high altitudes and erosion. This period of erosion must have lasted a long time, for in places the Upper and Middle Miocene was entirely removed, and the underlying strata laid bare.⁸⁶ After the post-Miocene interval of high altitudes, the Pliocene period of depression was initiated, during which, not only the coast, but also the valleys which had been developed during the previous period, were

Flinty Monterey Shale (Middle Miocene), Santa Barbara County.

(Photograph by Arnold, U. S. G. S.)

filled with delta deposits, while the hills were worn down nearly to base-levels. Remnants of these delta deposits are found on the coast, in the river valleys and in the great valley, and are particularly well exposed in the San Benito and Salinas valleys. Most probably an orogenic movement took place at the close of this Pliocene period of sedimentation, over a large part of the West Coast, which caused the upthrust of the mountains in western Humboldt county, of the granitic Montara mountains, of Mount Diablo, and the buckling in the drainage of the San Benito valley which forced the San Benito river to find an outlet through the Pajaro valley. These orogenic deformations antedate the post-Pliocene epeirogenic

uplift of the Coast region. These mountain-making movements were, however, not adequate to efface the peneplain, and the general altitude of the coast was not affected; the base-leveling process continued, and the peneplain was extended between the bolder masses of the disturbed district. At the close of the Pliocene the topography was that of an approximate peneplain, with numerous peaks and ridges above the general level, while the coast had the aspect of an archipelago.⁸⁷ The Pliocene formations have different names in the various portions of the Coast region. The Purisima formation forms the lower horizon of the Pliocene. Its fauna is transitional toward the Miocene and is related to the San Pablo, but the major portion is undoubtedly Pliocene. Part of the Wildcat series is contemporaneous with the Purisima. It consists of a series of conglomerates, fine sandstones, and sandy shales, and is named after its type locality near the mouth of Purisima creek, San Mateo county.⁸⁸ In the northern Coast range, near Eel river, the Pliocene is represented by the Wildcat series. This terrane occupies a large part of Humboldt county, north of Bear River ridge. At Ferndale the series is about one mile thick, consisting of clays, sands, sandstones, and conglomerates; the clays are most abundant at the bottom, the sands and sandstones predominate in the middle, and the gravels in the upper portion. Toward Scotia the beds become more arenaceous, indicating an approach to the shore line of the basin of deposition.⁸⁹ Along the coast, in the San Francisco peninsula and southward, the Merced consists chiefly of sandstones, with local admixtures of clayey material; occasionally there are thin lignite seams, and near the north end is a thin bed of volcanic ash. It is one mile thick, and rests unconformably upon the Franciscan.⁹⁰ In the river valleys of the Coast region the Merced is represented by the Paso Robles formation, a fresh-water deposit of approximately horizontal gravels, and sandy and marly clays, unconformable with the Miocene. These gravels are generally vigorously sculptured, forming a series of cliffs. The Paso Robles is also found west of the Santa Lucia range. In Lake county the Cache Lake beds belong to the Upper Pliocene, and the eruptions of andesites (asperites) appear to have been contemporaneous.⁹¹ On the south side of the bay of San Francisco the Upper Pliocene is not represented, but a pre-Merced heavy series of volcanics was laid down above the Upper Miocene (Orindan and Tramp). This series consists of the Lower Berkeleian, Upper Berkeleian, and Campan formations, principally tuffs and lavas. In the Upper Berkeleian an extensive succession of fresh-water deposits is contained, called the Siestan formation, and in the Campan are

some small lenses of limestone.⁹² Along the western border of the San Joaquin valley the Pliocene is represented by the Tulare formation, a thick stratum of gypsiferous sands and clays, which are exposed at intervals. They lie conformably upon the San Joaquin clays, and it is not always possible to distinguish between the two. These beds might be correlated with the Orindan beds.⁹³

In Santa Barbara county the Pliocene is represented by the Fernando formation, clay and clayey shale, sandstone, and conglomerate, the last two being oil-bearing at Summerland. This formation contains probably at its base the Upper Miocene strata, and at its top, part of the lowest Pleistocene. It rests generally unconformably upon the Miocene, and local unconformities occur within the series.⁹⁴ In passing southward along the western foothills of the Sierra Nevada, the Tertiary and Cretaceous strata are found resting nearly horizontally upon the upturned strata of the metamorphic series. At the point, however, where the Sierra Nevada turns westward, near Fort Tejon, the Tertiary strata are suddenly elevated at a high angle. This transition probably indicates a line of faulting, of which the northern continuation is apparently followed by the San Joaquin and Sacramento rivers.⁹⁵

(To be Continued.)

Antimony is found in many gold and silver ores, and when these ores are smelted the antimony combines with the lead of the charge to form antimonial lead. By this indirect means a considerable amount of antimony is produced, though it goes on the market as antimonial lead, for which there is a large demand and from which the metallic antimony is never separated. At present China produces the greatest quantity of antimony ores. France, Italy, Austria, Bohemia, Turkey, Mexico, and New South Wales are all considerable producers, and many other countries contribute lesser amounts to the world's supply. Japan was at one time a large producer, but her known deposits are now reported to be much depleted. The low prices now prevailing do not permit profitable production in the United States, as most of the known antimony deposits are in parts of the country where freight rates and wages are high. According to reports received by the United States Geological Survey, no antimony ore was shipped during 1908, though some was mined and held at Burke, Idaho.

The Bohemia mining district, in Lane and Douglas counties, Oregon, is described in a brief report by D. F. MacDonald, of the U. S. Geological Survey. The ore deposits are fissure veins which contain free gold, and have been developed by several mines. Mr. MacDonald sketches the general geology, the ore deposits, and the mining development of the district, and includes notes on the mode of ore deposition.

NEW ZEALAND PLACER MINES.

In 1908, 53 New Zealand dredging companies, employing 504 men, produced 56,554 oz. gold, valued at £221,089, according to the *Australian Mining Standard*. The expenditure for the year amounted to £180,704. These companies are capitalized at £455,500 and have a total recorded production of 488,794 oz., equal to £1,898,309. The dividends paid have amounted to £685,059. The corresponding figures for 37 mining and sluicing companies are: men employed, 420; capital, £424,650; gold won in 1908, 17,896 oz., equal to £69,940; expenditure in 1908, £75,455; total gold won since registration, 240,798 oz., equal to £789,707; total expenditures, £727,625; total dividends, £161,478.

Among the important localities for placer gold is the Ourawera valley in Otago. The Round Hill Mining Co., Ltd., successor to the Round Hill Synd., Ltd., has here a concession for working 140 acres of alluvial ground. Water is conveyed more than 50 miles and used at a pressure of 130 lb. The gold is fine and is saved, with a small amount of platinum, by means of angle-iron riffles and cocoanut matting. The company is capitalized at £50,000 and has paid £3248 in dividends from a total production of £115,747. In 1908, gold to the value of £9673 was produced, the expenditures amounting to £7032.

In the same neighborhood is the Ourawera Gold Mining Co., which has a claim of 40 acres at Round Hill, and is one of the most successful mining ventures that has been launched in Southland. According to the *New Zealand Mines Record* it commenced operations a little more than 12 years ago, with a nominal capital, fully subscribed and paid up, of £3000. Since then it has produced 9689 oz. of gold, valued at £38,563, and paid in dividends £12,415. Of late years it has almost ceased to be profit-earning, but it is still active, and has prospects of again returning rewards to shareholders. At the last half-yearly meeting the directors, in their report, stated that their anticipations of six months ago had not been realized. The ground worked had been irregular in depth, and generally much poorer than was expected, and the gold won had just about cleared expenses. The elevator had been shifted to Italian Gully, which is supposed to be the richest part of Round Hill, and the ground would be tested very soon. An aerial tramway had been erected, which, worked by the hydraulic winch, should effect considerable economy in the removal of stones and logs, as its operation would be quicker than that of a dredge. The value of the gold won during the half-year was £957, and the total expenditure was £985 0s. 2d. The assets of the company were valued at £3143 8s. 3d., and it had no liabilities except that to its shareholders for the paid-up capital.

Production of tin in Bolivia, according to Alfred A. Winslow, Consul at Valparaiso, amounted to 65,863,891 lb. in 1908, against 60,891,116 in 1907. The great Potosí mines produced nearly one-half of the entire output. On the tin exported the Bolivian Government in 1908 collected an export tax of \$240,279 United States gold.

PROPOSED LAW GOVERNING OIL LANDS.

The following act has been proposed in a bill introduced in the House of Representatives at Washington by S. C. Smith of Bakersfield. It provides, in Section 1, that public lands of the United States in the State of California chiefly valuable for mineral oil or asphaltum may be acquired under the provisions of this Act, and not as placer mining claims.

Sec. 2. That any citizen of the United States over the age of 21 years, and any person who has filed his declaration of intention to become such citizen, may file a declaration, under oath, with the register and receiver of the land district where such land is situated that he intends to claim and improve or cause to be improved for the oil or asphaltum thereon a tract of land, describing it, not exceeding 160 acres. If such land be surveyed, it shall be located by legal subdivisions, and if unsurveyed, it shall be located in rectangular form. In no case shall a claim be more than one mile in length. Such oath shall state that the affiant believes such land to be chiefly valuable for its deposits of mineral oil or asphaltum and distinctly his reasons for so believing; that he intends to make or cause to be made a bona fide effort to produce oil or asphaltum on said land in paying quantities; that he has not previously claimed any land in the same county under the provisions of this Act. Upon filing said declaration, the declarant shall pay to the receiver a fee equal to 25c. per acre of the land claimed, and thereupon the register shall enter such application upon his books, and no entry or filing shall thereafter be received for said land until such claim has been abandoned, as herein provided. But nothing herein contained shall be held to deny or abridge the right to enter said lands for the purpose of discovery and development of metalliferous minerals nor the assertion of a mineral claim thereto.

Sec. 3. That at any time within three years from the filing of the claim aforesaid the claimant or his assigns may file an application for patent. Such application shall show the applicant's right to or interest in said claim; that there has been made such drillings or excavations on said claim as enables the claimant to produce oil or asphaltum, or both, in commercial quantities; the character and extent of the improvements thereon; that the land is valuable for its deposits of oil and asphaltum and is sought chiefly for the oil and asphaltum therein contained, and that it is the bona fide intention of the applicant to produce such products therefrom in commercial quantities; if the application be made on behalf of one or more individuals, that each of them is a citizen of the United States over the age of 21 years, or that he has made his declaration of intention to become such; if on behalf of a corporation, that it is duly organized under the laws of some State or Territory, and has a valid charter authorizing it to take, own, and operate such property. Application on behalf of an individual shall be made by himself; on behalf of two or more, by either of them; and on behalf of a corporation, by the president, vice-president, or secretary thereof. At final proof documentary evidence shall be submitted as to matters of record; and as to the character of the land, the improvements, and produc-

tion there shall be furnished the testimony of two disinterested witnesses. No individual or corporation shall be a party to final proof proceedings under this Act on more than one claim: Provided, that if there are any veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits known to exist at date of filing such application for patent, title thereto shall not pass under any application, entry, or patent under the provisions of this Act, but are hereby expressly declared to be reserved therefrom, and such known veins or lodes shall be subject to location and entry by any qualified person or persons under the provisions of the existing United States mining laws applicable thereto: Provided, however, that any declarant who discovers any vein or lode bearing asphaltum, gilsonite, elaterite, or other like substances within the limits of the land included in his declaration or entry under this Act shall have the preferential right for a period of 90 days after discovery of such vein or lode within which to locate same under the provisions of the general mining laws of the United States, and must file with the register and receiver of the land district where the land is located a copy of the location notice.

Sec. 4. That upon receiving and filing an application for patent such notice shall be given and such proceedings had as are required for final proof on a mineral entry. If the final proofs are satisfactory, patent shall be issued upon payment to the receiver of the sum of \$5 per acre.

Sec. 5. That proceedings under this Act shall not give the claimant, before patent, any right to the surface of said land for agricultural, grazing, nor for any other purpose than that permitted by this Act, nor the right to fence or enclose the land (except corrals for protection of domestic animals), nor the right to take any wood or timber therefrom, except fuel for domestic purposes used thereon or in the vicinity of the lands by those engaged in the development of the oil or asphaltum thereon.

Sec. 6. That during each year after the filing of said declaration and before final proof the claimant or his successors in interest shall pay to the receiver a sum equal to 50c. per acre of said claim, or submit proof, supported by two witnesses, that he has expended during said year an equal sum in a bona fide effort to discover and produce oil or asphaltum on said claim or on land at a point within one mile of said claim, where no discovery of oil or asphaltum has been made in a shaft or well within three miles of said claim.

Sec. 7. That the following shall constitute an abandonment of a claim under this Act: First. Failure to make the annual payment or the expenditure herein required. Failure to file proof of such expenditures shall be prima facie evidence of a failure to make such expenditures. Second. Failure to apply for patent within the time specified. Third. Filing a declaration of abandonment with the register of the land office.

Sec. 8. That anyone holding and owning a valid mining claim for land chiefly valuable for the oil or asphaltum thereon may abandon said mining claim and re-enter the same under this Act, or so much

thereof as he is entitled to enter under this Act, in the following manner: He shall execute and deliver to the register of the land office an instrument in writing surrendering and conveying to the United States all right, title, and interest in and to said land. Said instrument shall be executed and acknowledged so as to be entitled to be recorded under the laws of the State where the land is situated. Upon delivering said instrument to the register, together with the fee for recording the same in the county where the land is situated, the mining title shall be extinguished, and the party surrendering the title may thereupon make his entry as herein provided. The register shall immediately cause said conveyance to the United States to be duly recorded in the county where the land is situated.

Sec. 9. That an Act entitled "An Act to authorize the entry and patenting of land containing petroleum and other mineral oils under the placer mining laws of the United States," approved February 11, 1897, and all other laws, so far as they allow oil or placer asphaltum claims upon the public lands in the State of California, are hereby repealed, but nothing in this repeal shall affect proceedings heretofore begun to acquire title under any of said provisions of law so repealed.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

F. A. A., Mogollon, New Mexico.—Hematite.

W. H. S., Columbia, California.—Pyrite and arsenopyrite in quartz.

W. H. B., San Francisco, California.—Clay containing a little pyrite.

D. F. D., Bodie, California.—No. 1, anglesite and hematite; No. 2, quartz with a little olivine; No. 3, pyrite in quartz; No. 4, specular hematite and limonite.

J. S. L., Ibapah, Utah.—No. 1, fluorite and pyrite; No. 2, a light green iron mineral (too small in amount for determination), giving a weak test for arsenic. No trace of copper, nickel, silver, or lead.

C. H., Guanajuato, Mexico.—(a) rhyolite with crystals of magnetite and cerussite on the surface; (b) rhyolite discolored by hematite; (c) rhyolite with crystals of magnetite; (d) rhyolite with hematite and magnetite; (e) slate containing a little pyrite; (f) quartz or vein material in decomposed schist or slate; (g) quartz in what was probably a slate; (h) rhyolite.

L. N. W., Nevada City, California.—No. 5, impure chromite, showing slickensides; No. 6, quartzose schist, mostly quartz, discolored by limonite; No. 7, a highly decomposed schistose rock; No. 8, highly decomposed schistose rock, now largely kaolin; No. 9, a decomposed quartzose schist discolored by hematite; No. 10, hydromica or hornblende schist containing quartz and pyrite; No. 11, a decomposed quartzose schist discolored by hematite.

ANDEAN PLACERS.

Goldfields in Peru and Bolivia east of the Andes have been described by W. M. Conway before the Royal Society of Arts. On the Beni river below the gorge at Guanay is an old lake basin filled with gravel carrying as much as \$4.23 gold per cubic yard. On the neighboring Inambari river gold has also been found. In both cases deep and flat-lying gravels occur. Companies have been formed to mine them. The various experts who have examined these gravels have tested surface gravels only. At Incahuara, however, many pits were dug and the ground was explored to a depth of 16 ft. and found to be rich. At no place has bedrock been reached. Neither has the bed of either river been examined. Only one method of working these gravels is practicable, and that is by dredging. There is not grade enough for sluicing. At Incahuara there are no boulders, the largest stones being little bigger than a man's head. Most of the reaches of the lower Inambari, except where torrential side streams enter, are also void of boulders. On both rivers the ground is loose, a mere mixture of stones and sand without hard clay. The current of neither river at proposed dredging points is swift enough to make trouble for a dredge. In flood time it can float over and excavate the banks or can be worked in a paddock. During low water it can work the bed of the stream. The transport of dredges to these remote places is difficult and costly.

The extent of the two dredging grounds is not known. The only part of the ground yet examined thoroughly is the Incahuara basin. This contains 10,000,000 yd. of workable gravel to a depth of 30 ft. Its surface has been sampled and has nowhere been found to yield less than 38c. per cubic yard, while large areas yield an average of at least \$1 and in many places much more. The bedrock value is likely to be much higher, and so is that of the actual bed of the stream. An average of 75c. per cubic yard is not an extravagant estimate. At this rate the Incahuara basin alone contains \$7,500,000 worth of gold. For 100 miles below the Incahuara basin it is believed that the Beni gravels yield gold. There are numbers of places where it has been definitely found.

On the Inambari a much longer stretch has been actually sampled than along the Beni, and as much as \$5.30 gold per cubic yard has been obtained. The Inambari, therefore, is likely to yield as much gold as the Beni. The lower tributaries of both rivers contain alluvial gold. Indications point to the conclusion that this part of the eastern slope of the Cordillera is a real goldfield of great size and importance. Its southern limit seems to be about the latitude of Mt. Illimani, but its northern limit is unknown. That it reaches far to the north of the Inambari valley is probable. Gold is reported on the Yucayli river and elsewhere, but the information is at present vague.

Tin is won by dredging at Tongkah or Puket, in Siam. According to *In Tinland*, The Tongkah Harbor Tin Dredging Co.'s dredge No. 2 worked 282 hours in March and produced an output of 270 piculs, equivalent to 18 tons of clear tin.

COMPOUND CORNISH PUMPING ENGINES.

Written for the MINING AND SCIENTIFIC PRESS
By W. PERCY GAUVAIN.

A misapprehension seems to be current as to the working of the compound Cornish pumping engine, hence I venture to offer a few remarks on the latest type, which may be of interest. In the first place, it would be as well to study the general principles which govern the working of the Cornish engine. It is hardly necessary to mention that an engine working on the Cornish cycle has simply to lift the pump-rods and draw in a charge of water. On the down stroke, the engine being in equilibrium, the weight of the rods forces up the water. The pump-rods should therefore be heavier than the water load, any extra

it is lifting the pump-rods, is about twice the speed of the water stroke, and for this reason the suction pipes and valves should be large, generally two suction valves and one delivery valve being employed. The Cornish engine used for mining work is usually more economical than when it is used for waterworks purposes, for the reason that as a mining engine the weight of the pump-rods usually far exceeds the water load, while the balance weight on the waterworks engine is little in excess of the load on the plunger. There is, however, a limit to the number of expansions, for increasing the weight and velocity of the moving parts puts greater stresses on the pump-rods and connections, so that steam of a higher pressure than 40 or 50 lb. cannot be used effectively. It will be seen, therefore, that there would be no extra economy in using steam, say at 150-lb. pressure, in the single-cylinder Cornish engine, for the number of expansions is limited to four or five. At

Fig. 1.

Fig. 2.

weight over the water load, plus the friction of the engine and pumps, being taken up by means of balance-bobs.

The Cornish engine takes advantage of the momentum of the pump-rods to enable it to use steam expansively—in fact, the rods are to it what a fly-wheel is to a rotative engine. The energy stored in the rods is expressed by the formula $\frac{W}{2} \frac{V^2}{g}$, where W is the weight of the moving parts, V the velocity in feet per second, and $g = 32.2$. It will be seen, therefore, that the degree of expansion depends on (1) the weight of the moving parts, and (2) the velocity which they attain, and as the weight is constant for a given engine, any increase in the degree of expansion employed increases the value of V. For the purpose of expansive working, the speed of a Cornish engine during the steam stroke, that is, when

Fig. 3.

Fig. 4.

the same time, there would be no advantage in compounding the engine if only low steam-pressures were used.

The idea of compounding the Cornish engine originated with Hornblower, and several engines were erected, by Woolf, Trevithick, Sims, and Gribble. In 1810 Woolf introduced his compound engine into Cornwall. In 1814 one of his engines, working at the Wheal Abraham, attained a duty of 35 millions. It should be observed that up to 1856 the duty was calculated on the basis of one bushel of coal equivalent to 94 lb.; after that date 112 lb. was substituted for the bushel. This engine in May 1816 attained a duty of nearly 57 millions. After this date the duty decreased, and it did not exceed the average of the best single-cylinder engines.

For low steam-pressures the Cornish cycle is un-

questionably the most economical, and engines working on this cycle have a much lower steam-consumption than any other type.

The adoption of high-pressure steam, with its resultant economies, led to the introduction of the compound Cornish type, working with steam pressures up to 150 lb. per sq. in. This type of engine was introduced by Davey, who has applied it in a number of cases with successful results. Henry F. Collins has, in the issues of the MINING AND SCIENTIFIC PRESS of February 20 and 27 last, written two interesting articles on 'Cornish Pumps and Pumping Engines', and he clearly shows why the Cornish engine has been so largely adopted, and why it seems likely that it will continue to be adopted in the future, in spite of competition from other types of pumping engines. I cannot, however, agree with a portion of his article in the issue of February 27. In order to prove his assertion that little if any economy is secured by the compound over the ordinary single-cylinder engine, he takes two examples of engines in use, a 90-in. Cornish engine about 40 years old, and a compound Cornish engine about five years old. The efficiency of the old Cornish engine is shown to be 90.16%, while that of the compound Cornish engine is 85.6%. I venture to suggest that an efficiency

Diagram illustrating distribution of steam in a Compound Cornish Engine.

Fig. 5.

of 90.16% is impossible on such an engine as he describes. This engine has eight plungers, each 16 in. diam., and the friction in each gland, that is, provided they are kept without leakage, will be considerable. It also has the old type of Cornish pitwork, with plunger set-offs, with, of course, extra guides and rubbing boards, which means extra friction. It is not reasonable to suppose that the old Cornish type with eight plungers can have a greater efficiency than the new type with only three plungers, and the latest design of straight-line pitwork. The additional cylinder on the compound Cornish engine will absorb some power through friction, but this will be small compared with the amount absorbed in the pitwork. The above efficiency is what is known as the mechanical efficiency of the engine and pumps, and it is an extremely good engine, built and erected with the greatest of care, that can show an efficiency of 85%. The fact of having a plunger slightly out of line, necessitating a tight gland to prevent leakage, will

make an appreciable difference in the mechanical efficiency.

Not much value can be placed on the coal-consumption figures mentioned, as they are only approximate, no coal being weighed. It is not good practice to take the duty of an engine on the basis of foot-pounds of work done per 112 lb. of coal used. It gives no information as to the efficiency of an engine, as it not only takes into account the evaporative efficiency of the boilers, but also the loss through radiation and leakage of steam-pipes, etc. Commercially it is correct, as it gives the work done for so much coal burned, but every engineer should endeavor to split up each portion of his plant, and find out in what particular part the losses are occurring. In order to get a proper and true test of the efficiency of an engine,

Fig. 6.—Compound Cornish Engine.

the best method is to take the duty on 1000 lb. of steam, that is, the number of foot-pounds of work done per 1000 lb. (or any number agreed upon) of steam passing through the engine. The indicator cards taken from the Cornish engine, and reproduced in Mr. Collins' article, call for no comment, but not so the cards from the compound Cornish engine. It is at once evident that the valve-gear of the compound engine needs adjusting. The absence of compression, so advantageous in raising the steam in the clearance spaces to the initial pressure, is most marked. The action of the valves which are controlled by the differential gear is not as it should be. The vacuum, so beneficial to a Cornish engine, is also poor. This engine is obviously working with a light load, while the Cornish engine is fully loaded. Taking the above points into consideration, it is not reasonable to compare the performances of the two engines. My experience of the compound Cornish engines, and I may say I have under my supervision three of them, in-

cluding the largest yet built, is exactly the opposite to that of Mr. Collins. They are without doubt considerably more economical than the ordinary Cornish type.

In 1900 I had the opportunity of testing the compound Cornish engine at the Basset mines, in Cornwall, comparing the figures with an 80-in. Cornish engine on the same mine, the result being enormously in favor of the compound type. For the same work done, about one half of the amount of coal was used. Part of this enormous saving must, of course, be credited to the greater evaporative efficiency of the new boiler plant, but by far the greater amount was due to the lower steam-consumption of the compound type. The accompanying diagrams were taken from the large compound Cornish engine at the Waihi mine, the largest of this type yet built. The dimensions of this engine are as follows: high-pressure cylinder, 60 in. diam. by 6 ft. stroke; low-pressure cylinder, 110 in. diam. by 12 ft. stroke; plungers, 23 in. diam. by 12 ft. stroke; total lift at the time cards were taken 1010 ft.; steam-pressure, 150 lb. per sq. in.; speed of engine at time cards were taken, 6 strokes per minute. Fig. 1, 2, 3, and 4 are indicator cards taken November 1908, and give the horse-power generated at each end of the two cylinders, a total indicated horse-power of 469. The water horse-power is 389, and the mechanical efficiency is $\frac{389 \times 100}{469} = 82.9\%$. Fig. 5 shows these four cards combined, all on one common scale, and is reproduced for the sake of illustrating the steam distribution in a compound Cornish engine. It is not a correct diagram of the work done; in order to get this, the low-pressure cards must be multiplied by 6.7, which is the ratio between the high-pressure and low-pressure cylinders. The parts shown in black indicate the losses during the cycle of operations. It will be observed that there is a fairly large loss, owing to excessive compression in the high-pressure cylinder, and the same applies to a smaller extent in the low-pressure cylinder. This is due to the engine being slightly out of balance when these cards were taken. By increasing the balance-weight, and thereby reducing the compression, the mechanical efficiency would be greater, and the losses less. A certain amount of compression is distinctly advantageous, as it raises the steam-pressure in the clearance space and reduces initial condensation. The drop in steam-pressure between the top and bottom of the high-pressure and low-pressure cylinders is not great, the drop between the two cylinders being larger. This engine will later on be fitted with a wiper cut-off gear on the low-pressure cylinder, so as to more nearly equalize the work done in the two cylinders. Calculating on the same bases as Mr. Collins, namely, an evaporation of 8.5 lb. of water per pound of fuel, the duty of this engine is 108,000,000 foot-pounds.

Fig. 6 is a line diagram illustrating the general arrangement of the engine. The high-pressure and low-pressure cylinders are on either side of the main gudgeon, and the pump-rods, which are 24 in. square at the surface, at the high-pressure end. This construction reduces the stress, as only a portion of the work has to go through the centre of the beam. The cylinders being some distance apart, it is economical to

place a re-heater, supplied with steam at boiler pressure, between them.

In the smaller sizes of engine the two cylinders are placed together at the end of the beam, opposite to the pump-rod. This puts more stress on the beam, but tends to reduce steam consumption. The compound Cornish engine is particularly adapted to metalliferous mines, where shafts are usually smaller than in coal mines, and where two rods would occupy too much space.

In the engine above described it will be observed that the number of expansions is about twelve, as compared with four in the ordinary Cornish type. The following are a few advantages of the compound Cornish engine over the single-cylinder Cornish type: (1) Ability to use high-pressure steam, with its resultant economies. (2) The initial strain is reduced, being only about 1.3 times the mean, as compared with twice the mean in the old Cornish type, and this notwithstanding the large number of expansions. (3) The cost of the engine per horse-power does not exceed the single-cylinder type. The water-load is about 30 lb. per square inch, as compared with about 16 to 20 lb. in the older type. A compound Cornish engine at the Waihi mine having a low-pressure cylinder 70 in. diam. by 8 ft. stroke and high-pressure cylinder 35 in. diam. by 6½ ft. stroke, with pump-cylinder 16½ in. diam. by 10 ft. stroke, is working with a water-load of 31 lb. per square inch and running at 8½ strokes per minute. (4) Ability to employ larger units. A single-cylinder Cornish engine of the same horse-power as the large Waihi engine would require a cylinder of about 135 in. diam by 12 ft. stroke, which would present great difficulties in casting.

In conclusion, it is obvious that the advantages of the compound Cornish engine over the ordinary Cornish type are so great that everything points to the adoption of the compound engine where it is intended to use the Cornish cycle, or where, through want of room in a shaft, it is only possible to have a single line of pump-rods.

Utah contains important coal reserves. The areas known to contain workable beds are estimated by M. R. Campbell, of the U. S. Geological Survey, to aggregate 13,130 sq. m., and there are in addition 2000 sq. m. of which little is known, but which may contain workable beds. The original contents of these fields are estimated by Mr. Campbell to have been 196,458,000,000 short tons. The first production of coal in Utah was reported in the census year 1870, when 5800 tons were mined. The output exceeded 1,000,000 tons for the first time in 1900, and reached its maximum of 1,947,607 tons in 1907. The total production since mining began in 1870 to the close of 1908 has amounted to 20,683,974 short tons. On the basis of one-half ton of coal wasted for every ton of coal mined and marketed, the exhaustion during this period has amounted approximately to 31,000,000 short tons, or 0.016% of the original supply.

The Gwendollin mining concession, owned by Jardine, Matheson & Co., in Korea, is being developed with success. A stamp-mill is being operated.

VACUUM SLIME-FILTERS AT GOLDFIELD.

Written for the MINING AND SCIENTIFIC PRESS
By ALFRED MERRITT SMITH.

The Butters vacuum filter plant at the Nevada Goldfield Reduction Co.'s mill at Goldfield, Nevada, is one of the earlier installations, and various methods of operation have been tried during the last four years, with a view to securing the most economical results. At the time the filter plant was installed it was not deemed practicable to erect the 'semi-gravity' type, whereby the stock-pulp is gravitated into and out of the filter-boxes as required from pulp-tanks placed respectively above and below the filter-boxes. The mill is situated on level ground, hence the filter-boxes were elevated quite high in order to secure sufficient dump-room for future accumulation of slime residues. About 12 ft. below the level of the filter-boxes is placed the one stock-pulp tank required, from which the pulp is pumped directly to and from the filter-boxes. The pumping is accomplished by a 6-in. Butters centrifugal pump, provided with the usual arrangement of valves for reversing the operation. The vacuum-pumps are two in number, of the Smith-Vaile 10 by 10-in. single type, and the working vacuum varies from 15 to 25 in. The filter-boxes are three in number, having 15 leaves each, 45 in all. Leaves of a special design by E. S. Leaver have been in use for over three years, the essential difference from the Butters leaves being that grooved wooden slats are used as a filling for the canvas leaf, instead of the canvas being sewed upon a cocoa matting filler.

Assuming general familiarity with the operation of vacuum slime-filters of the modern type, I will briefly describe the evolution of our filter work here to the present stage. It is known in milling circles where slime-filters of the Butters make have been adopted, that there is a continual enrichment of the wash water, or wash solution, by osmosis, which in the filtration of high-grade slime will result in material losses of gold. For example, the cakes having been formed on the leaves and the excess pulp returned to its tank, clean water is pumped or gravitated into the filter-boxes for washing, and the vacuum again applied to draw wash water through the cakes. But this clean water, coming into contact with the comparatively large area of slime cake, pregnant with gold solution, immediately absorbs and diffuses a portion of the gold and cyanide. After the required amount of this wash water has been drawn through the cakes by means of the applied vacuum, the excess of 'wash' is run back to a tank, to be used again for the same purpose, carrying with it an increment of gold and cyanide. This gold and cyanide in the wash is cumulative, increasing with each cycle of operation. The quantity of water necessary to replace that which is drawn through the leaves, and also that which is discharged with the residue in ordinary work, is not sufficient to prevent a gradual enrichment of the reserved wash.

It was our early practice here, when the wash water had increased in assay value from nothing to about \$1.50 or \$1.75 per ton, to discharge the whole

of it into the battery solution tanks. As the original crushing is done in cyanide solution, this provided a way to save a part of the loss. A fresh supply of clean water was then taken in for filter wash. This, however, did not save the cyanide and gold remaining in the wash water which was necessary to run out the slime-residue, amounting to several cents per ton of dry slime in treating the high-grade ores of Goldfield. Double washing was next tried. The cakes were first thoroughly washed with weak barren sump-solution, the whole of the excess wash being returned to a separate tank. The boxes were re-filled with clean water, the vacuum applied for five minutes, to re-wash slightly, the cakes were dropped, and the excess of water returned to the water tank, enough water being retained to discharge the residue in the usual way. In theory this method seems almost perfect, as the loss of gold by osmosis is reduced to almost nothing, and the volume of working mill-solution is not materially increased by an additional five-minute water wash. The objections were, first, a double exposure to the air and the washing action, frequently causes much of the cake to loosen and drop off from the leaves prematurely, and second, more time and pumping is necessary to complete a cycle of operations. The first of these objections is not serious, as it cannot overcome the primary object, that is, the prevention of gold loss by osmosis, for this is obtained by saving all of the first wash solution, none of which is used to sluice out the residue.

The method now in use, which allows the filters to be worked at their full capacity, and at the same time minimizes the loss by osmosis, is as follows: The cakes being formed and the stock pulp returned, the boxes are filled with weak barren sump-solution and sufficiently washed. When the wash is completed, an excess of wash-solution is pumped back to a storage tank, enough being retained to flush out the residue. The discharged residue is run into a tailing dam, settled, and clear solution is drawn off by means of a gate or weir, to a pit, from which it is pumped back to the mill, to be used again as filter wash or as battery solution. Clean water is run into the residue pond to the amount of fifteen or twenty thousand gallons per day, as a further wash and to absorb and save a portion of the gold-bearing solution which remains in the residue. This water is returned to the mill, and is ordinarily sufficient in quantity to preserve the equilibrium of the mill solutions.

Below is a sample copy of the record kept for each filter-box charge, showing the distribution of time in a complete cycle:

| Charge No. 4987. | | June 4, 1909. | | |
|-------------------------------------|---------|---------------|------|----|
| Filter-box No. 2. | A.M. | Hr. | Min. | |
| Filling filter-box with stock pulp. | 6:52 to | 7:13 | | 21 |
| Period vacuum applied | 7:13 " | 8:18 | 1 | 5 |
| Pumping back excess pulp..... | 8:18 " | 8:35 | | 17 |
| Pumping on wash solution..... | 8:37 " | 9:00 | | 23 |
| Time washing | 9:00 " | 10:00 | 1 | |
| Dropping cakes | 10:00 " | 10:07 | | 7 |
| Pumping back wash | 10:07 " | 10:22 | | 15 |
| Discharging residue | 10:22 " | 10:27 | | 5 |
| Total time of cycle..... | | 3 hr. 33 min. | | |
| Tons of solution from pulp..... | | 4.53 | | |
| Tons of wash through cakes..... | | 3.05 | | |
| Thickness of cakes..... | | 1 in. | | |
| Specific gravity of stock pulp.... | | 1.21 | | |

PELLEY, ROSS, AND GRAVEL RIVERS.

By J. KEELE.

*The country through which the Yukon river and lower portion of the Pelly river flow appears to be a dissected plateau. An originally low rolling country has been elevated to a height of about 4000 ft. above sea-level, and carved by stream action into a series of long, gently sloping ridges or dome-shaped hills, whose summits may be remnants of the original plateau. Following the Pelly river eastward, these hills become higher, and merge into mountains more or less rugged, with crests standing at a much higher elevation than the plateau region; from 6000 to 7000 ft. above sea-level. These mountains extend eastward to within 40 miles of the Mackenzie, and are then flanked by a narrow belt of foothills, which gradually decline in elevation until a fairly level plain is reached, standing at an elevation of about 600 ft. above sea-level.

The western plateau region is underlain by what are generally regarded as the oldest rocks of the region. These consist chiefly of various crystalline schists, of both sedimentary and igneous origin; but also contain a subordinate quantity of later intrusive rocks, including granites, diorites, and andesites, which generally still retain their massive character. The heterogeneous character of the rocks included within the mountain province precludes any lengthy description. Briefly, those on Ross river consist chiefly of sedimentary rocks, including slates, cherts, and quartzites, together with a few small intrusive bodies of granite, diorite, and andesite; while those on the Gravel river consist of sandstones, limestones, dolomite, and conglomerate. Intrusives are seldom seen. The plain lying east of the foothills, and bordering Mackenzie river, is underlain by soft sandstone and conglomerates, probably of Cretaceous age.

Prospecting for gold began on Pelly river as early as 1882. For some years subsequent, miners working on the gravel bars made as much as \$10 to \$20 per day, their operations being confined to the lower portion of the river. Since then prospecting has been carried on along the greater part of the river and many of its tributaries, but no mining of importance has yet been done in the region. Fine colors of gold are found in the gravels over a large area, but no coarse gold has yet been discovered. For the last few years work in the district has been confined to the streams entering the Pelly from the south, between Lapie and Hoole rivers. These streams head in a high range lying south of and parallel to the course of the Pelly. Along the base of these mountains lies a wide valley, floored with gravel and containing several lakes. This valley is separated from the Pelly river by a line of rocky hills, through which the streams have cut channels. The gravels of the valley contain fine and coarse colors of gold, and a portion of the gold, concentrated from them, is caught in the bedrock in the lower portions of the streams tributary to the Pelly. The Stewart River region, to the north of the Pelly, resembles the country in the

vicinity of the latter, in many respects. Coarse gold was found in that region about ten years ago, and almost every year since then discoveries of more or less importance have been made. Two serious difficulties, however, hard to overcome, prevent the Stewart River country from becoming a successful mining camp. These are underground water and lack of adequate transportation to ensure a supply of provisions for miners all the year round. The same difficulties apply to the Pelly River country. A good deal of rich ground which could be worked by the open-cut method was mined in the Stewart country, but individual miners have never succeeded in deep digging where underground water occurred abundantly. At least two parties of miners, and probably more, have prospected of late years on the Ross river, but without success. Charles Wilson, who has prospected on the upper portion of the river during the last two years, got colors of gold in one small creek which flows into the south branch of the MacMilan river, but found no coarse gold. My experience corroborates these statements. It is possible that coarse gold may exist on bedrock on either the Ross or Gravel rivers, or their tributaries, but the apparent absence of fine gold in the gravels tends to discourage any hope of it being found there. A fact, frequently commented on by men who accompanied me, was the marked absence of quartz, either in the bedrock or the wash gravels, along the route traveled from the Pelly to the Mackenzie.

There appears to be a close connection in the Yukon Territory between the crystalline schists and the placer deposits. In the Pelly valley these rocks appear to occupy a belt extending for a distance of about 10 miles on each side of the river, which flows generally parallel to the strike. In the vicinity of Campbell creek, however, the Pelly river turns northeastward, while the belt of crystalline schists continues southeastward to the Francis river. Fine gold is found in the gravels all along the Pelly, from Campbell creek to the Yukon, while none is found above that point on the river. Small veins and stringers of quartz are abundant in the schist, and quartz pebbles form a considerable percentage of the wash gravels along the Pelly. Mr. Henderson tested a few bars on the Pelly, at and above Hoole canyon, using two sluice-boxes about 12 ft. long. He saved for me several pounds of the black sand which accompanied the gold. A grayish white malleable mineral in small scales, which I thought might be platinum, is abundant in this sand. The sample was submitted to Robert Johnston, mineralogist to the Survey, who states it to be ferro-nickel, a rare mineral, but of no commercial value in such small quantities. The bulk of the black sand is composed of magnetite and garnet.

Quantities of drift lignite are found along the lower part of Campbell creek, but the seams from which it is derived were not found. There is probably a small Cretaceous area lying on the schists in this vicinity, similar to the one on the Pelly some distance below Ross river. Drift lignite is found along Gravel river where it enters the plain bordering the Mackenzie, and which is no doubt derived from seams in the adjacent Cretaceous.

*Abstracted from Summary Report, Geological Survey Branch, Department of Mines, Canada, 1908.

ALASKA SURVEYS NOW UNDER WAY.

All the Alaskan field parties of the U. S. Geological Survey are now at work or on their way to the interior. The surveys and investigations of 1909 include 14 parties, which are widely distributed over Alaska. These parties comprise 12 geologists, 7 topographers, and 3 engineers. The surveys are carried on under the direction of Alfred H. Brooks, who left Seattle for Cordova on the first of July. From Cordova he will proceed up Copper river and make a brief visit to the Nizina district. Circumstances permitting, he will then go by overland trail to Fairbanks, and later will pay a visit to the Berners Bay and Eagle River districts, in southeastern Alaska.

Adolph Knopf, geologist, began work in the Berners Bay region on May 19, studying the geology and ore deposits in detail. On the completion of this work he will start for Eagle river, and will there begin work on a similar investigation. J. W. Bagley, with one assistant, is making a detailed topographic survey of the Eagle River mining district.

At the close of last year the general investigation of the two copper belts of the Copper River region was completed, and it now remains to make a more detailed study of the regions of present greatest economic importance. The area first to be investigated lies at the east end of the Chitina-Kotsina belt. This field not only affords the best exposures, but is also the region where greatest depth has been reached in developing the orebodies; hence it will yield more facts than other parts of the district, and has therefore been chosen for first investigation. F. H. Moffitt and S. R. Capps, who are to do this work, reached Valdez June 1 and reported a heavy fall of snow in the pass, which delayed them. They are now on their way to the interior.

U. S. Grant and D. F. Higgins sailed from Seattle on June 8 for Seward, where they will begin a reconnaissance of the eastern part of Kenai peninsula. Much prospecting has been done in this field during the last few years. It is expected that Mr. Grant will be able to complete the preliminary examination of the entire southeastern and southern coast line of the Kenai peninsula.

The policy of mapping the Alaskan coalfields in detail will be continued in the Matanuska field this season. R. H. Sargent, with one assistant topographer, began work about the middle of June. This force will be divided into two parties. Mr. Sargent's task will be to make a detailed topographic map of the most important part of the Matanuska coalfield, which will serve as a base map for special geologic investigations during 1910.

West of Cook inlet is a large unsurveyed tract in which, it is reported, there have been discoveries of copper lode deposits and placer gold. The Geological Survey this year despatched a double party to begin the survey of this extensive area. This party is in charge of D. C. Witherspoon, topographer, with whom is associated G. C. Martin, geologist. The party landed at Iliamna bay May 14. F. J. Katz will assist in the geologic work and C. E. Giffin in the topographic survey.

The extensive area lying between the Yukon and

Tanana has been the subject of investigation for several years. A reconnaissance map of this area is now completed, and much of the geologic work has also been done, but a considerable tract still remains to be covered. This work is being continued by L. M. Prindle, assisted by B. L. Johnson. The party will land at Circle about the middle of June and go southward, reaching Fairbanks about the first of August. Thence a trip will be made to the region southeast of Fairbanks, and later in the year the work will be extended into the area northwest of Fairbanks. The investigation of the surface water supply needed for placer mining in this field was begun in 1907, and as it is necessary to obtain records of stream-flow for a number of years before any generalizations can be made as to the run-off, these investigations have been continued this year. C. E. Ellsworth, who was detailed to this work, reached Fairbanks over the trail about the first of April, and has since been engaged in stream measurements in the Fairbanks, Baker, and Rampart districts. The first survey of the Chandlar and Koyukuk districts was made in 1899 by F. C. Schrader and T. G. Gerdine. That was the summer in which gold was discovered in this field. Since that time the Koyukuk district has been a continued producer in a small way, but in 1907 more valuable placers were found there, and some workable placers were found in the Chandlar district. This fact led to a demand for further work in this field, which is being carried on by A. G. Maddern. Mr. Maddern will reach the Chandlar district in the early part of July, and later will make his way overland to the Koyukuk district.

Between the lower Koyukuk and Seward Peninsula there is a belt about 150 miles wide which is practically unexplored. It is possible that this area may contain deposits of gold and coal. With the view of obtaining information on this point, P. S. Smith, assisted by H. M. Eakin, is carrying on an exploratory survey westward from Nulato to Norton bay, and thence to Council.

The Geological Survey has done more work in Seward Peninsula than in any other part of Alaska. The entire field has been covered by geologic and topographic reconnaissance maps, and some of the more important areas have been mapped in detail. In addition to this, special reports have been published on the tin deposits and on the gold placers. Investigation of the water resources—an important feature to the placer miner—was begun in 1906. This work is being continued through another year. F. F. Henshaw, assisted by G. L. Parker, is expected to reach Nome about the middle of June.

The North Lyell, in Tasmania, is developing into one of the richest copper mines in the world. Last half-year closed with an addition to the ore reserves of 169,121 tons, making 710,333 tons blocked out and ready for stoping, and the ore contains 6% copper.

A mining concession has been granted an Italian company in the district of Huchang in North Pyongan, Korea. Reports from Seoul are to the effect that some valuable deposits have been developed recently.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CLAIMS—APEXING VEINS.

The owner of a lode mining claim has the right to the ore beneath the surface of his claim in a vein not having its apex there, subject only to the right of the owner of the claim where such vein apexes to follow it downward on its dip.

Mammoth Mining Co. v. Grand Central Mining Co.,
29 Sup. Ct. Rep. 413, March '09.

FAILURE TO MARK BOUNDARIES OF MINING CLAIM.

When the purchaser of a mining claim took it without defined boundaries, and during the continuance of his claim erected no monuments or corner posts, so that the boundary lines of his claim could be readily traced, he assumed at his own peril the risk of intervening rights of third persons.

Protective Mining Co. v. Forest City Mining Co.,
(Wash.) 99 Pac. 1033, Feb. '09.

OIL AND GAS LEASE—CONSIDERATION.

A lease for oil and gas, for a money bonus as consideration, did not bind the lessee to drill for oil or gas or pay money in lieu of doing so; but it left it optional with him to do so or not. The lessor in such a lease could not annul or revoke it merely on the ground of want of mutuality.

Pyle v. Henderson, (W. Va.) 63 Southeast, 762,
Jan. '09.

DEFECTIVE LOCATION NOTICE GIVES COLOR OF TITLE.

Where in an action to quiet title to a mining claim against a prior location, a discovery was not proved, a defective location notice was held a sufficient color of title, when coupled with possession gained under a peaceful entry, to warrant a recovery, and where it appeared that the defendant had no legal rights in the disputed ground.

Protective Mining Co. v. Forest City Mining Co.,
(Wash.) 99 Pac. 1033, Feb. '09.

EFFECT OF DISCOVERY BEFORE NOTICE OF LOCATION.

The fact that mineral is not discovered on a claim until after the notice of location is posted, and the boundary marked, is immaterial, where there have been no intervening rights, and where the discovery is the result of work subsequently done by the locator, his possessory rights under his location are complete from the date of such discovery.

Protective Mining Co. v. Forest City Mining Co.,
(Wash.) 99 Pac. 1033, Feb. '09.

MINING CLAIM—QUIETING TITLE.

A person seeking to quiet title to a mining claim against a prior locator is not required to allege that he had actually discovered minerals on the claim; nor is he required to excuse the absence of such allegations by alleging that his location notices showed that his act was a re-location of abandoned ground. In such case it is sufficient to allege ownership and possession and the adverse claim of the defendant.

Protective Mining Co. v. Forest City Mining Co.,
(Wash.) 99 Pac. 1033, Feb. '09.

APPROPRIATION OF LAND BY A RAILROAD—RIGHT OF OWNER OF MINERALS.

A railroad company appropriating land for its right of way or other purposes secures not only the surface, but also so much of the underlying minerals as may be necessary to properly support the surface for its use. And where the owner of the surface had prior to such appropriation by the railroad, conveyed the underlying coal with sufficient mining rights to enable the grantee to remove it, regardless of its effect upon the surface, such grantee was entitled to be compensated by the railroad company for any part of the coal necessary for the support of the surface.

Diltz v. Plumville R. Co., (Pa.) Atl. 1072, Jan. '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

GEOLOGY OF THE DISSEMINATED LEAD DEPOSITS OF ST. FRANCOIS AND WASHINGTON COUNTIES. By E. R. Buckley. Missouri Bureau Geol. and Mines. Vol. 10, pt. 1, pp. 259, pt. 2, Atlas. Jefferson City, 1909.

This, Mr. Buckley's final report for the Survey of which he was sometime director, treats of one of the most important mining areas in the United States. The work is based upon studies extending intermittently from 1903 to 1908. It presents in great detail, by means of maps and sketches, the mode of occurrence of the ores, including the baryta near Potosi. The maps will attract attention, especially because of the large number of fault lines which have for the first time been traced out. Mr. Buckley refers the deposits genetically to the descensional class, and believes them to have been formed through the action of ground-water in part derived direct from the surface and in part finding its way into the Bonnetterre limestone from the La Motte sandstone below.

EL PASO FOLIO. By G. B. Richardson. U. S. Geological Survey, Washington, 1909. Price 25 cents.

To mining men the principal point of interest in this folio will be the portion discussing the tin deposits of the Franklin mountains. According to Mr. Richardson, present developments do not warrant prediction. The chief question concerns the abundance of ore which, as he sensibly remarks, can only be determined by further work. "Conditions, however," he states, "appear to warrant intelligently directed development, and the entire granite outcrop might well be prospected for new occurrences of tin ore." The excellent map and the text of the folio will be of great service to any one undertaking this work.

Catalogues Received.

The BLAISDELL Co., Los Angeles, Cal., has just issued its Catalogue K, describing the Blaisdell patent vacuum filter leaf.

The JEFFREY MFG. Co., Columbus, Ohio, has recently published Bulletin No. 23, describing its propeller fan for mine ventilation and 'boosting'.

The NEW YORK ENGINEERING Co., New York, has lately published a pamphlet on the Empire Hand Prospecting Drill for prospecting placer ground. It will be sent to anyone interested.

The HENDRYX CYANIDE MACHINERY Co., Denver, Colo., has just published its Catalogue No. 6, which describes and illustrates the testing works of, and different machinery carried by, this concern.

The C. O. BARTLETT & SNOW Co., Cleveland, Ohio, in its Catalogue No. 30, just from the press, gives 130 pages of illustrations of machines made by the company, and also numerous installations of all sorts.

The WESTERN ENGINEERING & CONSTRUCTION Co., San Francisco, Pacific Coast agent for the Robins Conveying Belt Co., is distributing the latter's Bulletin No. 20, on the subject of 'Hoisting and Conveying Machinery for Power Stations'. They will be glad to send it to anyone interested.

Mica.

The total value of the mica produced in the United States in 1908, according to statistics compiled by D. B. Sterrett for the United States Geological Survey, amounted to \$267,925. The production of sheet mica amounted to 972,964 lb., valued at \$234,021, a decrease of 87,218 lb., and \$115,290 from 1907. The production of scrap mica amounted to 2417 short tons, valued at \$33,904, a decrease of 608 tons and \$8896. The value of the imports into the United States fell from \$925,259 in 1907 to \$266,058 in 1908, or slightly less than the domestic production. The mica produced came from ten States, the most important of which, named in the order of the value of production, were North Carolina, South Dakota, Colorado, Alabama, and Virginia.

EDITORIAL.

SURVEYS have been completed for the projected railroad from Toluca, in the State of Guerrero, Mexico, down the canyon of the Balsas river to the Pacific. A region reputed to contain large veins of gold-bearing pyrite with moderate amounts of copper would be opened by this line. Mr. G. T. Shaw, the chief engineer, states that the enterprise is in the hands of British capitalists who are identified with the Popo Packing Company.

CONSERVATION is not attracting attention in America only. At a recent meeting of the Faraday Society in London, Mr. E. R. Taylor presented the subject of conservation of water power from the American standpoint. In the discussion the advanced position of Germany was pointed out, as also the many difficulties to be met in Great Britain as a result of the high cost of land. The subject is one requiring much study, but evidently, if we are to profit by our neighbor's mistakes, there should be also some action.

DEATH has taken from us one of our special contributors, Mr. John A. Reid. He was one of the younger men of our staff, but one whose loss we shall feel keenly. A man of charming personality and sterling character, with a passion for service and a genius for friendship, well trained, and with high ideals of professional conduct, he was of the type of American mining engineer of whom we are all proud. Standing as he did at the threshold of an apparently successful professional career, he could ill be spared, but his example remains—that of one who looked well to his foundations, and did his work manfully to the last.

HONOR is due the brave men who explored the West and laid the foundation of the present development of its resources. Among these hardy pioneers, the one-armed veteran of the Civil War, Major J. W. Powell, was a leader. He was a scientific observer and kept the great problems always in mind. He devoted his life to science and his country, and died poor. It is a peculiar pleasure to know that the proposal to erect a monument to him by public subscription has met with instant and popular approval, and that the committee in charge is receiving a large number of small checks. We hope there will be many more, as the lesson of such a monument lies as much in the popular response as in the life of the man honored.

CONVENTIONS are a feature of American life, and the season for these summer gatherings is almost here. The Irrigation Congress will meet at Spokane from August 9 to 14, and the Trans-Mississippi Commercial Congress at Denver from August 16 to 21. In September the American Institute of

Mining Engineers will visit Butte, Spokane, Seattle, and Tacoma, continuing their trip into October in order to stop at Salt Lake. The Mining Congress at Goldfield, October 11 to 16, will close the list of those in which mining men have special interest. These meetings bring out much helpful and stimulating discussion, and it cannot be doubted that the country at large is benefited. Perhaps the larger benefit to those taking part arises from the broader acquaintance acquired with regions and men.

JOKING has often proved dangerous. Mr. James Taylor, one of the State Mine Inspectors of Illinois, has now found it so. While on a visit to Pennsylvania he told the oft-repeated story of the Miners' Committee which waited on the mine manager and wanted him to measure the air. Being told that he could not do so because the company had failed to furnish an anemometer, they went to the company's office and threatened a strike if an 'automobile' were not furnished the boss. It seems that the humor of this story is not appreciated by the miners of Pennsylvania.

SOUTH AMERICA is being brought steadily into closer relations with the United States. A direct line of steamers has been put in service between New Orleans and Buenos Aires. The new Peruvian line to Panama shortens the time from Lima to New York and San Francisco, and it is announced that a great bank, endorsed and facilitated by the Administration, is being formed to encourage trade between this and South American countries. The immediate returns on the capital of such a bank are not likely to be large, but the incidental profits should be satisfactory. The bank will stimulate the development of new industry. The existing producers in every department of activity, mining and agricultural, are bound to the old established export houses by long extensions of credit. Participation in this old business is impossible. The new bank will find its opportunity in the opening of new territory by railroads and irrigation projects, and in the underwriting of securities for the development of mining enterprises. Such expansion naturally will call into existence a new crop of middle-men, free to make commercial alliances independent of the old régime. To make such operations effective ample steamship service is requisite; this brings up anew the everlasting question of a shipping bill which will enable this country to hold its own against foreign subsidized fleets.

COMPETITION in Manchuria is intense. We are assured on the one hand that Fushun coal, produced, by the way, in the Japanese zone of influence, is "the best steaming coal in the Far East." Equally positive declaration is, however, made that the Kaiping coal, mined by an Anglo-Chinese company, "is superior to any being mined in the Far East," and there has been much diplomatic discussion regarding the true status of the Fushun mines. All this means merely that two railway companies are contesting for traffic. The Chinese Eastern has put in reduced rates from Mukden to Vladivostok on beans, the principal article of export. The South Manchurian railway still hauls the bulk of the crop to Dairen,

and is accused of discriminating against Niuchang. The particular discrimination charged bears a family resemblance to our Spokane rate case. The defense is that Dairen is an ice-free port, and that the real objections come from owners of warehouses for winter storage at Niuchang, who see a profitable business rapidly disappearing. The difficulty is to be met, it is announced, by the Chinese opening a new ice-free port in Lien Shan, Gulf of Pechili, about 200 miles north of Shanhaikwan. These moves and counter-moves on the part of Russians, Japanese, and Chinese emphasize the fact that the controversies are founded, after all, on economic causes and are not unlike our own troubles between rival cities and ports. It is well to cultivate a certain calmness in discussing 'outrages' in the Far East.

Copper Prices and Production.

Copper continues a mystery. Not even by the entrails of a fowl does any oracle venture to predict the future. The plain pragmatist of the street is sure he has not been favored with a view either of the 'insides' of the market or of the oracular chicken. We know who buys the gold and the silver, the iron, the lead, and the zinc, but to all query as to whither goes copper no answer comes. Concerning the hereafter and copper the Sphinx is silent. And, incidentally, who is the Sphinx—especially the copper Sphinx, that can seal the lips that so many would smite to speech? The Copper Producers' Association issues statistics that give non-committal summaries. The smelter output for May was the largest on record. It reached 118,300,000 pounds. In June it was but little less. The domestic stock has decreased, while the visible increase abroad was about 22,000,000 pounds. The consumption, however, is not ascertainable except by those who are close to the market. The openness so characteristic of transactions in other materials does not apply to copper. But the great smelters continue not only to produce but to prepare for a heavier output; dividends are being paid; and new copper mines are being developed and equipped. This can only mean that the plight of the copper smelters is not as difficult as it seemed a month or two ago. It seems probable that the consumption of copper has actually been greater than had been generally assumed. The high prices quoted at the summit of the boom were mere exaggerations. The junta that fixes prices on the metal exchange could publish pretty figures, but the buyer held aloof. It has been affirmed by leading independent copper producers that insignificant deliveries were made at a higher price than 22 cents per pound. The high price prevented accumulations of stocks abroad, but great quantities were carried in this country. The public entertains the impression that copper must command about 15 cents to be distinctly profitable. As a matter of fact, in the last twenty years the average has reached 15 cents only seven times. During the other thirteen years the average price was 11.96 cents per pound. The average American production during that period was 257,527 tons per annum, whereas the amount in 1906 was 409,414, and in 1908, which is conceded by Messrs. Aron Hirsch & Sohn to be a record year for con-

sumption, it was 408,928 tons. The increase in known copper reserves within the same period has evidently kept pace with the augmented demand. There is no reason to anticipate a marked elevation in the price; the copper miner must bend his energies toward economy; he must keep down his mining costs, and not try to smelt with small units. The day of small works, and of smelting with barren flux, is over. The demand for copper is good, and it will grow, but so will production by the mammoth corporations, and competition from South American mines, which yield precious metals in important quantities, must be met.

Mexican Mining Law.

Great excitement stirred the foreign colony in Mexico a year ago because Señor Olegario Molina, the venerable and energetic Minister of the Interior, or Fomento, as Spanish people suggestively term the office, had evolved a project for a mining law which imposed restrictions on foreign corporations. It is not peculiar to Spanish-America that politics are matters of such delicacy that the truth is passed along under the breath instead of by open speech, lest dust of difficulty be raised. This even involves the foreigner, who often talks loudly, but in circumlocution of the real point of interest. The motive behind the mining law as first proposed has never been declared, and perhaps we are bound to the same cautious treatment of what all men know who know anything of the problems confronting the Administration of the Republic today. Are there not Reyist demonstrations even now in evidence? Meanwhile President Diaz is so guiding affairs as to prevent a lapse of the onward and upward movement of Mexican development. Foreigners must be considered as well as citizens when it comes to legislation.

The new project for a mining law, of which we print the first chapter in translation elsewhere in this issue, has passed the House of Deputies, and will probably be confirmed as it stands by the Senate in September. Under it the foreigner labors under no disadvantages, except as regards a buffer zone which refers particularly to the frontier with the United States. Within that zone, as the statute runs, "Title to mining property may not be issued in favor of foreigners who denounce *pertenencias* within a zone of eighty kilometres along the dividing line with foreign countries, if they have not previously obtained special permission from the Executive of the Union. This will be required even when the denouncement be made jointly by foreigners and citizens of the nation;" and again, "Foreign corporations are incapacitated from denouncing or acquiring, by whatever title, mining properties or real estate rights in the same, within said zone." It is also provided that if a foreign corporation should stand in law entitled to such properties by virtue of inheritance or adjudication by the courts, it must transfer the same to legally competent ownership within the period of one year. This follows closely a like provision in the Federal Statutes of the United States touching mining claims within the jurisdiction of the Territories. The prohibition above mentioned applies also, under the new Mexican project

of mining law, to those not citizens of the Republic.

With these exceptions, the status of a foreign corporation is merely that of a legal person, free to hold property and transact business subject only to the municipal law and to treaty restrictions, which latter are practically nil. In effect, a foreign corporation is thus liable only to the extent of available assets within the Republic, and is taxable thereon, regardless of its capitalization. A foreign corporation accordingly enjoys advantages superior to those of companies constituted under Mexican law.

The liberality, fairness, and good sense of the Mexican Mining Law have won the encomiums of distinguished jurists in America and other countries. The unit of surface is small, consisting of one hectare, equal to 2.47 acres, but any number of hectares may be grouped for purposes of title, thus reducing the cost and inconvenience of making application for patent. Possibly the term patent should not be applied at all, since ownership in fee simple is not conceded. The right obtained by title is superior to a leasehold, and yet forfeiture is more swift and absolute than occurs from failure to pay accruing taxes on patented land. Also the previous existence of ownership does not cloud a subsequent title in the absence of a court decree, if the property has become open to denouncement. No extralateral rights accompany mining property, but the *pertenencias* may be so grouped as to cover an area that will protect the miner on the dip of his vein. The utmost facilities are granted for the economical operation of mines, the industry being declared a public utility, which opens the way to expropriation under circumstances defined by the Civil Code. No lax provisions are offered for holding claims through the performance of assessment work, which may be evaded, as is so often done in the United States. The only means for retaining control of mining property is by filing a claim and paying the requisite fees. The claim does not then lie, as a mere assertion of possession, on the books of the Mining Agency, but must be pressed forward to title within a limited period, and the prescribed fees must be paid. If an application be allowed to lapse it costs money to relocate, so that the temptation to locate great areas and hold them by fraud, as can be done in this country, is effectually dissolved. The Mexican Mining Law is at once liberal to the individual, and protective of the public interest; it prevents abuse of the National domain, and requires its economic use as the means for retaining rights therein. Even outside of the statute, the spirit of fostering the mineral industry is shown. Recently a Government subsidy was obtained for the sinking of a deep shaft to explore the veins at Guanajuato. This is a broad extension of the principle that mining is a public utility. The city of Guanajuato has much to gain through demonstration of deeply seated ore deposits; the advantage to Guanajuato would be also a gain for the Nation. It is a remarkable instance of fomenting industry through what we choose to call paternalism. Though unusual, it is no more than a logical application of the principle underlying the subsidizing of railroads and the encouragement of certain forms of effort through a protective tariff.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. A. WORCESTER is in Denver.

HENNER JENNINGS is in San Francisco.

F. LYNWOOD GARRISON has been in San Francisco.

H. FOSTER BAIN is visiting Nevada City, California.

JAMES H. MORAN, of Sonora, Mexico, is at Los Angeles.

R. A. F. PENROSE is expected in San Francisco shortly.

C. J. BANDMANN is examining mines in Sonora, Mexico.

D. H. PETTINGILL is at Parlier, Fresno county, California.

E. S. KING, of the Ivanhoe mine, Kalgoolie, is in London.

ROWLAND FEILDING is in Italy, inspecting alluvial deposits.

W. E. DEFTY will be at Los Angeles the next two months.

E. NESBIT is with the Grasselli Chemical Co. at Cleveland, Ohio.

ROBERT D. GRANT has returned to Los Angeles from New York.

C. B. E. DOUGLAS is at Minas del Tajo, Rosario, Sinaloa, Mexico.

EMERSON GEE has returned to Los Angeles from Sinaloa, Mexico.

ROBT. J. BONNEMORT is at the North Star mine, Kofa, Arizona.

E. M. HAMILTON is with the El Rayo M. & D. Co., Santa Barbara, Mexico.

J. H. BAKER, representing Phelps, Dodge & Co., will leave soon for Honolulu.

E. H. WEBSTER has gone to the Mina la República, Ocampo, Chihuahua, Mexico.

H. ABBOT TITCOMB has arrived in London after extended travels in the Orient.

JOHN O. NORBOM has been examining mines in Mariposa county, California.

J. V. BOHN is general superintendent for the Tennessee Copper Co., at Ducktown, Tennessee.

H. C. DAVEY, manager of the Guadalupe quicksilver mine, of Los Gatos, California, was in San Francisco.

BRAYTON P. CAMPBELL has been appointed superintendent of the Eureka-Windfall cyanide mill, at Eureka, Nevada.

CHAS. M. ROLKER is expected in California, from London, in connection with the examination of dredging ground at Folsom.

FRANK D. PAGLIUCHI and B. G. COBB have opened an office at Dawson, Y. T., to engage in mining engineering and metallurgical work.

R. B. HERGARDT, general manager for the Old Dominion Copper Co., has recently returned to Globe, Arizona, from California.

LUCIEN EATON, recently with the Iron Belt and Shore mines, is now superintendent at the Cliff shaft of the Cleveland Cliffs Iron Co., Ishpeming, Michigan.

E. H. SIMONDS has returned to San Francisco from Mazuma, Nevada, where he has been starting the new mill of the Darby Ore Reduction Company.

Obituary.

JOHN A. REID died in Stockton, California, on July 4. During the winter of 1907-8 Mr. Reid went into Lower California on professional work, and there contracted pneumonia which later developed into tuberculosis and caused his death. He was a graduate of the University of California and for some time teacher in the University of Nevada. He was a special contributor to the MINING AND SCIENTIFIC PRESS and the author of numerous bulletins and papers relating particularly to the geology of the Sierra Nevada. He was a keen observer, and while engaged in general consulting practice took time to put his observations on record for the benefit of others.

General Mining News.

ALASKA.

All the steamers of the first sailing from San Francisco and Seattle have arrived at Nome and have added about 2000 to the population of that city.—The Wild Goose Mining & Transportation Co. has begun operations in the Council City district for the summer.

ARIZONA.

COCHISE COUNTY.

The cross-cut from the 135-ft. level of the Monarch group cut 2 ft. of ore that assays between 3 and 4% copper. The ore is a sulphide in a limestone gangue. Two shipments have been made from the Morrow and Chamberlain claims of this group that averaged about 9% copper, 12 oz. silver, and \$3 gold per ton.—Surface work has uncovered a vein of lead-copper ore on the claims of Joe Larriau adjoining the Monarch group.—Development work on the recent find on the 1250-ft. level of the Denn is opening an excellent body of ore. The vein has widened to the width of the drift and picked samples have assayed from 30 to 40% copper.—The Bisbee Coalition Co., which recently took over the claims of the North Bisbee Extension Co., has acquired the Eureka group. On the former group the development is being carried on at the fourth level.—The Superior & Pittsburg Copper Co. is applying about \$50,000 per month to reduction of its indebtedness.

GILA COUNTY.

The Warrior Copper mine is shipping 60 to 70 tons of ore per day to the smelter. The winze is down 300 ft., but is soon to be sunk to the 1000-ft. level.—A station is being cut at the 900-ft. level of the Arizona-Colorado mine. On the fifth and eighth levels cross-cuts have opened some excellent orebodies. L. E. Phillips is in charge of the work.—The Inspiration Copper Co., in the Miami district, has taken over the Black Copper group of claims joining it. The claims have been prospected with diamond-drills and the cores have shown a good copper content. The Joe Bush shaft on the Inspiration ground is down 290 ft., mostly through a 2½% concentrating copper ore.—The roadbed of the Gila Valley railroad has been graded to Cordova and will be completed to Miami in a few weeks. The excavation for the foundations of the Miami mill is nearly completed.—A 4-ft. vein of ore has been opened by a cross-cut from the 300-ft. level of the Limestone shaft of the Superior & Boston Copper Co. The boilers for the new hoist at the McGaw shaft are in place and the hoist nearly ready for operation. The shaft is down 426 ft. A cross-cut is being driven from the 400-ft. level of the Gardner shaft to cut the Black Oxide vein.

GRAHAM COUNTY.

The raise from the 700 to the 500-ft. level in the Fumazole mine of the National Mining Exploration Co. near Safford is finished and over 150 ft. of cross-cuts have been run this month. F. A. Woodward is manager.

MOHAVE COUNTY.

The winze from the 250-ft. level of the Tom Reed mine is down 40 ft. in good ore.—A new hoist has been installed on the Ruth property and drifts are being run on the 70-ft. level. Assays of the ore run between \$27 and \$50 per ton.—At the Golconda mine the main shaft is being sunk at the rate of 4 ft. per day. The drift from the third level has been driven 200 ft. along a 4-ft. vein of ore that assays 50% zinc. One carload is being shipped to the smelter.

PIMA COUNTY.

L. J. and N. Corda have bonded their North Prosperity property in the Olive district to Eastern capitalists for \$35,000. L. J. Corda will have charge of the property.—The shaft on the old Chesterfield group is down 200 ft. and a cross-cut is being driven from that point to the vein. Surface work recently cut ore that assayed 5% copper, 13% lead, 22 oz. silver, and \$3 gold per ton at a depth of 26 ft. M. R. Chamberlain is superintendent.

PINAL COUNTY.

William P. Staffel has purchased a one-half interest in the Gold Bell group of claims near Kelvin from John B. Sebian.—The interests of the American Mines & Exploration Co. in the Gila and Ray Consolidated companies have been purchased by Bernard M. Baruch for \$1,000,000.

The adit of the Kelvin Tunnel Site Co. cut a vein of chalcopryite ore when in 600 ft., giving 400-ft. backs. Tom Hall is superintendent.

YAVAPAI COUNTY.

Lester Jackson, holding a two-year lease on the Gladiator mine, is opening that and the adjoining War Eagle group through the Gladiator shaft. A cross-cut from the 600-ft. station cut an iron-copper-zinc vein, and the War Eagle gold-silver vein, carrying a low percentage of the base metals. This has been driven on and two stopes put up 40 ft.—Enoch Williams received the second payment of \$2000 for the Baltimore group.—The Penn-Arizona Mining Co. is to install the largest electric hoist in Arizona at the Walker mine in the Mudhole district.

YUMA COUNTY.

(Special Correspondence).—The Lewisohns of New York, who recently took over the Planet group, announce that \$500,000 will be expended in development.—The Daly Mines Co. has let a contract for the sinking of a 135-ft. shaft on the Vulcan group.—The Shannon Copper Co. has secured control of the Blue Slate group and is arranging for extensive work. The claims contain several large deposits of copper ore with a good percentage of gold.—The Inland Copper Co. has installed a 50-hp. hoist at the main shaft.—Several rich finds have been recently made in this section, and a small rush is on from nearby points. The building of the Swansea-Arizona railroad is bringing many remote points in close touch with the commercial world. With shipping facilities assured, local mining men have commenced the active development of properties throughout the district.

Bouse, July 12.

A gasoline hoist is being installed at the Heart's Desire mine. The double-compartment shaft is down 100 ft. and cross-cuts started from that point. T. C. Varden is in charge of the work.—Cross-cuts are being driven from the 100 and 200-ft. levels of the Little Butte mine to cut an 18-ft. vein opened on the surface.

CALIFORNIA.

AMADOR COUNTY.

Lessees are shipping ore from the Onelda to the Selby smelter that assays from \$30 to \$80 per ton. The Onelda Mining Co. spent a large sum in equipment and development, but failed to open this rich shoot.—Development in the South Eureka mine is opening the recent find with satisfactory results.

CALAVERAS COUNTY.

The Ritter mine near Mountain Ranch has been sold to George E. De Golia for \$10,000.

DEL NORTE COUNTY.

The Doctor Rock copper mine has been sold to an Eastern syndicate by Mrs. F. C. Mariow. There is a large outcrop on the property that assays well in copper.—The Cleopatrina Mining Co. has applied for a patent to its ground.

ELDORADO COUNTY.

The shaft of the Mt. Pleasant mine at Grizzly Flats is unwatered to the 300-ft. level, and lateral work has been started at that point. The water is to be lowered to the 500-ft. point and drifts run on the vein.

INYO COUNTY.

The Buckeye Mining Co. is arranging to erect a 50-stamp mill. The ore is low-grade, averaging about \$4 per ton, but there is a large tonnage that can be worked in an open-cut.—The vein at the old Modock vein has been cross-cut and driven on from the lower adit, opening a body of lead-silver ore that assays 600 oz. of silver per ton. John Kelly is in charge of the work.—The Bishop Creek Milling Co. has installed a Sullivan 9-drill compressor and a Pelton

water-wheel. The shaft will be sunk to the 265-ft. level and a cross-cut driven to the shoot cut on the level above.

MONO COUNTY.

The Alden Mining Co. has run a 75-ft. adit and sunk a 90-ft. shaft on its property. Several cross-cuts from the bottom of the shaft have penetrated good ore.

NEVADA COUNTY.

The 20-stamp mill of the Giant King mine near Washington has been started. The mill at present is being operated by steam-power, but the company has purchased the Washington ditch and water-right and will install a hydro-electric plant. A lower adit is being driven to cut the vein.

PLACER COUNTY.

The shaft at the Orpheum mine is down 162 ft. A 5-stamp mill has been purchased from the Risdon Iron Works and is being hauled to the mine. Charles Peach is superintendent.—The Herman Property Syndicate has paid off the \$11,000 indebtedness of the Herman mine and is re-timbering the air-shaft. E. B. Quigly is in charge of the work.—The Boulder Ridge Syndicate is operating the Patterson mine north of Penryn.—Harold Power is working the Hidden Treasure and Mountain Gate gravel mines through the Hidden Treasure slope.—Some excellent gravel is being taken out of the Bonanza mine at Gold Run. J. D. Stewart is superintendent.—The old Paragon channel has been cut by the adit at the Paragon mine. W. S. Fletcher is in charge of the work.

SAN BERNARDINO COUNTY.

The shaft on the Oro Belle is down 260 ft. and a drift run 325 ft. on the vein. On the 200-ft. level the cross-cut has intersected the vein and assays show the ore to be of milling grade.—The Todhunter lease is shipping ore. A winze is being sunk in milling ore.—A drift has been started at the 700-ft. point of the Big Chief adit along a streak of ore that assays about \$100 per ton. William L. Foster is manager.—The Eldorado-Searchlight Mining Co. is to install a mill and cyanide plant at the Old Bonanza mine. George Freeborn is president.—The Kramer Consolidated Oil Co. struck a flow of oil in its bore-hole near Kramer at a depth of 2930 ft. A large amount of gas is present and the oil is of a light quality. Two other companies are drilling in the same district.

SHASTA COUNTY.

A new adit on the Wild Bear claim of the Friday-Lowdon group above Kennett has cut a streak of good copper ore.

The Mountain Copper Co. has let contracts for the installation of new machinery at Keswick and Iron Mountain. Plans are ready for the construction of a new smelter across the creek from the old plant.—The Peterson group of claims near Heroult has been bonded to the Stauffer Chemical Co.—The Western Exploration Co. has given up the bond on the Spread Eagle group near Kennett and has bonded the Stowell group.

SIERRA COUNTY.

S. B. Graciar and H. P. Haley are to start work on their Hunch property near Alleghany some time this month.—C. L. Wilson has bonded the Metropolitan mine from William Reynolds. The mine has been opened by several adits and some good ore taken out.—A cross-cut from the 680-ft. level of the Alaska mine at Pike City intersected the vein and drifts are being run in both directions in good ore. George St. John is superintendent.—The water-right, flume, and Bonanza quartz claim of W. A. Lotspeich and Con Yorke have been attached for labor bills amounting to \$2500. There is also a lien of \$700 filed against the property.—The adit at the Antlers quartz mine has been cleaned out and work started on the vein. Tom Winrod is in charge of the operations.—The power-house of the Four Hills Mining Co. is being repaired and the adit re-timbered preparatory to starting the mine.—George F. Stone and associates, holding a bond on the Uncle Sam group, have started a shaft to cut the vein.—The adit on the San Fernando group has been cleaned out and re-timbered for 300 ft. A drift will be started shortly to cut the ore-shoot found in the level above.—The shaft at the

Gibraltar mine of the Kleffer brothers is being unwatered and will be sunk to the bedrock.

TRINITY COUNTY.

H. E. Crowell brought the 'clean-up' from the Union Hill mine to Weaverville. The company has an excellent bank of gravel and a good water supply.—The Enterprise is stoping ore that carries a high percentage of sylvanite and telluride ore. George S. Fenwick is superintendent.—The final clean-up for the season has been made at the Testy mine.—The Folsom Development Co. is drilling the Sykes and Ellery properties at Trinity Center to determine their value for dredging.

TULARE COUNTY.

A Los Angeles company has secured an option on some property in the foot-hills near Lindsay which shows some oil seepages and will commence drilling shortly. The land is in the heart of the Lindsay orange belt.

TUOLUMNE COUNTY.

F. E. Willetts has secured a lease and bond on the Anderson mine from E. N. Anderson. There are two shafts on the property that have cut a vein which assays \$50 per ton.—An 80-ft. adit at the Thompson mine near Tuttletown is opening some good ore.—A Huntington mill has been installed at the Santissimo.

COLORADO.

BOULDER COUNTY.

A 6-ft. vein has been opened by the lessees of the Highland Mary mine on Breece hill.—An electric hoist and new head-frame have been installed on the Vinnie property of the Golden Eagle Mining Company.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work is to be resumed in a few days upon the McClelland adit, now in a little over 7000 ft.—A fine body of galena ore has been uncovered in the upper adit of the Josephine mine, on Kelso mountain. The vein is from 14 to 18 in. wide, and assays from \$70 to \$80 per ton in silver and lead. J. R. Sapp is manager. For the last month shipments have been from 60 to 80 tons per week.—C. Runkle, holding a bond and lease on the Colorado Central-Allunde group of mines on Leavenworth mountain, will commence shipping within ten days. A streak of silver-lead ore from 2 to 8 in. wide, on the sixth level, assays from 275 to 550 oz. in silver per ton.—W. Farragher, leasing the Astor on Democrat mountain, has struck a vein of 175-oz. silver ore that is from 8 to 12 in. wide.—U. Whittier has resumed work upon the Dolly Varden group of claims on Griffith mountain.—The Jewell mine at Silver Plume has been purchased by S. H. Bradley from the Jewell Mining, Milling & Leasing Co.—S. Farout is developing the Lafayette property. The drift is following a streak of \$25 gold and silver ore that is from 4 to 6 in. wide.—B. J. O'Connell has started shipping from the Gambetta mine. The lead-zinc ore is being sent to the Linn concentrator for separation.—The Capital Mining & Tunnel Co., on Griffith mountain, is putting from 120 to 130 tons of ore per day through its concentrator. In addition to this a heavy tonnage of smelting ore is being sold at the local sampler. W. M. Cooper is manager.

Georgetown, July 11.

GILPIN COUNTY.

A test lot of ore was shipped from the Mackey mine in Elk Park to the sampling works at Denver to determine the best form of mill to be erected on the property.—Operations are to be resumed at the property of the Golden Rod Mining & Milling Co. on Silver creek. G. Battaja will be in charge of the work.—The Pendleton-Gomer Mines Co. has taken over the Gomer quartz mine and several placer claims in the Russell Gulch district. The shaft will be sunk 500 ft. from the 160-ft. level and cross-cuts run to the vein, which has assayed well in the upper level. A. A. Johnson is manager.

GUNNISON COUNTY.

The Crested Butte Coal Co. has opened a 6-ft. vein of coal 65 ft. below its former workings. The coal is of a good quality and the company will transfer its active opera-

tions to this vein.—The Waunita Coal Co. is opening some excellent coal properties below Somerset. Alex. Bowers is superintendent.

SAN JUAN COUNTY.

Hennings & Bastian have sub-leased the Tiptop property west of Eureka to Matt Sutherland and associates.—The adit on the Allerton property in Prospect gulch is in 400 ft.—The Esmeralda shaft has been unwatered to the second level and some good ore exposed.

SAN MIGUEL COUNTY.

Farrell & King have leased the Summit mine and the Gold King mill near Ophir. The tramway from the mine to the mill has been repaired and some excellent ore taken out.

SUMMIT COUNTY.

A new crusher has been installed at the Blue Flag mill on Baldy mountain. The last clean-up of the French Gulch Gold Mining Co.'s dredge amounted to \$18,500.—The International mine near Robinson is being re-opened. The mine closed down about two years ago, after shipping a small amount of ore from the 1100-ft. level.

TELLER COUNTY.

Seaver & Henry are shipping regularly from their lease in the Mattie L. mine.—A gold retort estimated to be worth \$5600 was sent to the U. S. Mint at Denver by Edward Gaylord, operating the Gaylord cyanide mill on Ironclad hill, and lessees of the Jerry Johnson and Arapahoe mines. The retort represented the clean-up on 1600 tons of ore.—Eighteen cars of ore were shipped during June from the W. P. H. mine on Ironclad hill by Oscar Gobleman, general manager for the Roach & Fogleman lease on the United Gold Mines Co.'s property.—The Forest Queen mine shipped two cars of ore that averaged \$35 per ton.—The Union Leasing Co. has secured a two-year lease on the Bonanza Chief on Beacon hill, and a shaft is being sunk from the surface near to the Hiawatha line.—Two cars of ore were shipped from the Morning Star mine on Bull hill.—The recent strike on the 1300-ft. level of the Vindicator is proving a bonanza, as an 8-ft. vein has been opened that assays \$100 per ton. A dividend of $1\frac{1}{2}$ ¢. per share has been declared.—The Doctor Jack Pot Mining Co. declared a dividend of $\frac{1}{2}$ ¢. per share, amounting to \$15,000.—A dividend of 2¢. per share was declared for July 15 by the Portland Gold Mining Co. The total amounted to \$30,000.—Word & Hill received a settlement of \$45 per ton for a shipment of ore from their lease on the Pharmacist mine.

IDAHO.

BLAINE COUNTY.

The Muldoon mill at Muldoon has been started and is turning out 50 tons of concentrate per day. There are 14 stopes opened in the mine, but at present one in the upper level is supplying the mill. Robert T. Tustin is in charge of operations.—The Independence and Cannonball mills are to be started shortly.

IDAHO COUNTY.

The drift on the lower level of the Buster mine has been run 100 ft. on the vein and is expected to cut the ore-shoot at any time. The company has taken up a water-right and power-site on Red river. J. F. Thorn is superintendent.—A raise from the 350-ft. level of the Penn-Dixie cut an ore-shoot that assays well. W. L. Sendker is superintendent.—A 14-in. vein has been cross-cut in the Black Diamond mine.—Brown & Hartman cut a 4-ft. vein on their Saylor group.—The Champion mine on Thunder mountain cut a 2-ft. vein on the 300-ft. level that assays as high as \$800 per ton. A. R. Balcom is in charge of the work.

KOOTENAI COUNTY.

A 400-ft. adit on the Black Jack group near Lane cut a vein from which samples were taken that assayed 15% nickel, 20% copper, 15% lead, and 25 oz. silver per ton. Thomas Gonyea owns the claims.

NEZ PERCE COUNTY.

Charles Hofstetter, of Spokane, and associates have secured a lease on 200 acres of State land near Kaniyah, containing asbestos deposits.

OWYHEE COUNTY.

A cross-cut in the Gold Crown mine cut a streak of ore that assayed between \$900 and \$1500 per ton. The mill is running successfully, having recently shipped \$14,000 worth of amalgam. L. Foester is manager.

SHOSHONE COUNTY.

The shaft being sunk from the 4500-ft. point of the Gold Hunter adit is down 100 ft. A cage has been installed and the shaft will be sunk to the 600-ft. level. Dennis Ryan is manager.—The adit of the Lucky Swede mine in the St. Joe district is being re-timbered and the company will have an orebody of shipping grade opened shortly.—The management of the Hercules mine is negotiating for the purchase or lease of the mill at the Tiger mine at Burke.—A deep adit is being driven on the property of the Alpena Copper Mining Co. near Wallace. There is a large amount of shipping ore blocked out in the mine and piled on the dump.—The Moonlight Mining Co., operating in Gorge gulch, near Burke, levied an assessment of 2¢. per share. It is proposed to drive an adit 3000 ft. to tap the vein at depth in the sulphide zone. J. N. Murphy is manager.—The Bunker Hill & Sullivan Mining & Concentrating Co. has paid dividend No. 142 of \$45,000.—A rich strike of nearly pure galena carrying 200 oz. of silver per ton was made in the Caledonia mine, and regular shipments are being sent to the smelter.—The Butte & Coeur d'Alene Mining Co. is sinking a shaft on its property east of Mullan and will cross-cut to the vein. A winze is being sunk in the ore.—A new Hancock jig with a capacity of 500 tons per day has been installed in the Morning mill.—The pay-streak of the Holy Terror mine has widened to about 3 ft. An adit is being run on the vein, to intersect the shaft, that will give 1200 ft. of backs. The ore assays 37% lead, 22 oz. silver, and \$8 gold per ton. Ole Holk is president of the company.—The Black Bear Fraction Mining Co. has opened a good body of milling ore and is to concentrate it in the Frisco mill. Peter Bernier is superintendent.—The Northern Light Mining Co. is opening an orebody that assays 11% copper and 2% lead. A prospect shaft on the property has opened a 14-in. vein of galena ore.—The Carney Copper Co. is driving an adit to open the vein at a depth of 500 ft. An upper cross-cut opened an 8-ft. orebody that averaged more than 3% copper.—Shaft sinking has been resumed at the 200-ft. level of the Bullion mine.—A 1040-ft. adit on the Manchester property cut a 6-ft. vein of fair milling grade. Joseph Blackburn is in charge of the work.

KANSAS.

CHEROKEE COUNTY.

The Hartford mine has resumed operations south of Galena since the zinc-blende has gone above the \$40 mark.—Waterhouse & Co. has purchased a 300-ton mill from the Webb City camp and will remove it at once to the Maggie Taylor lease at Galena.—The Lizzie D. mill on the Dwyer lease at Peacock is completed and will be started about the middle of this month. The ore here is of a sheet-ground formation, running 5%, and found at 180 ft. About 150 ft. of drifts have been run. The ore carries a 10-ft. face.

MISSOURI.

JASPER COUNTY.

The Optimo, O. K., and Lone Pilgrim, in the Sarcocite camp, have been consolidated under the management of W. L. Bramblet.—The John Nilson farm at Carl Junction has been purchased by the Lehigh Mining Co.—In Jackson Hollow the M. I. & O. mill has been overhauled and is again producing.—The Newsboy, in the Duenweg camp, is again working after an idleness of several years.—Work has been resumed at the Nortonia in the Chitwood camp.—Among the more recent mills ready for operation is the plant of Starkweather, Schweiart & McGill at Neck City.—Gray & Stevens are preparing to erect a mill for the treatment of the dump-ple on the Shifferdecker land west of Joplin.—Douglas & Co. is preparing to erect a 500-ton plant on the Luke & Ash ground west of Joplin. A double-compartment shaft is down 197 ft. in a sheet-ore formation.—The Carnation at Prosperity began opera-

tion of its new 300-ton mill on a lease of the Cosgrove ground. The shaft is down 285 ft. in a disseminated ore formation below the sheet-ground.—A rich strike was made at Carl Junction across the creek from the Mohler Smith.—New York miners are to begin the prospecting of a 160-acre tract at Bell Center west of Joplin, and have let the contract for 2000 ft. of drilling.

NEWTON COUNTY.

Southwest of Wentworth, on the Conway property operated by Joplin and Wentworth men, drifts have been cut at 30 ft. which show good mineral.—A shaft is down 70 ft. on the Poland, both galena and silicate being found.—In the Spring City camp the Plata company is taking up a rich stope.—Preparations are being made to develop a large tract between Spring City and Baxter Springs by the Granby Mining & Smelting Co.—A good strike of silicate was made in the Granby camp by Paynter & Stanley on the Reed ground.—A strike has been made in the Colored Lady lease and a new shaft will be sunk at once.

MONTANA.

MISSOULA COUNTY.

Supplies have been taken to the Monitor mine, five miles from Saltese, and the shaft is being unwatered. A copper vein has been proved to the 700-ft. level. H. F. Samuels and Ole Linn are managers.

NEVADA.

CLARK COUNTY.

The shaft of the Lucy Gray mine is down 300 ft. and a station is being cut at that point. An 8-in. vein was cut at 75 ft. that assayed \$165 per ton. A cross-cut will be driven to this and drifts run along it.—The Eldorado Crown Mining Co. has been incorporated to work the Crown, Queen, and Cross claims. Assays from the veins on these properties run between \$8 and \$14 per ton. It is proposed to build a mill and cyanide plant. George Bergman, John McGreer, and Henry Dickson are the principal stockholders.

DOUGLAS COUNTY.

The Spreckles Sugar Lime Rock Co. of San Francisco has bonded the Winters mine, 18 miles north of Gardnerville, for \$100,000. The property contains 200 acres in the Pine Nut range.

ESMERALDA COUNTY.

The cross-cut from the 450-ft. station of the Victor shaft of the C. O. D. mine cut a body of ore that resembles the rich ore of the district.—The Codd Mines Co. has secured an extension of its lease on the St. Ives property at Rawhide. A good body of ore has been opened on the 200-ft. level and the shaft will be sunk to the 1000-ft. point.

HUMBOLDT COUNTY.

The Monette Mining & Milling Co., in the Seven Troughs district, in the west cross-cut from the 400-ft. level of the shaft cut a stringer of high-grade ore.—The Kindergarten mill is running on ore from the Wihuja lease that runs about \$200 per ton. A cross-cut on the lower level of the Kindergarten is being driven to get under the richest point in the level above.

NYE COUNTY.

(Special Correspondence).—It is planned to commence the shipment of ore from the West Extension to the smelter at Needles. Ore valued at \$300,000 is blocked out in the main workings of the mine, and 125,000 tons of \$23 ore is piled on the dump.—The Rickard-Garberg lease at Pioneer has struck a large vein of milling ore on the 300-ft. level.—The Cliffords and Nays have commenced work on the driving of an adit at Elendale to tap the vein disclosed in the original locations at a depth of 100 ft.—The greater portion of the Jim Butler estate has been leased for a period of two years to H. C. Epstein and C. S. McCarthy. The lease comprises a portion of the Curtis, Eureka, and Sunset claims, and work will be commenced in the Fraction No. 1 shaft.—Placer mining activities at Manhattan continues to hold the attention of southern Nevada operators. At the Giffen lease on the Verde claim 100 yd. of gravel is handled every 24 hours.—On the Dividovitch lease a 15-hp. Witte gasoline hoist and 6-in. Cornish pump have been installed.—The Big Five is producing at the

rate of \$100 per day.—The Allison-Philbrick lease on Wednesday Fraction is installing a washing plant and expects to commence operations within a few days.

Rhyolite, July 11.

The Mayflower Consolidated Mining Co., in the Bullfrog district, has contracted with the Nevada-California Power Co. for electric power sufficient to operate the mine and mill. Underground work is being centered on the new shoot being opened on the 300-ft. level. The Alward lease on the property is down 65 ft.—The Skidoo Mining Co. has purchased the Epstein & McDonald lease and is now running the 15 stamps on company ore.—The bi-monthly clean-up at the Montgomery-Shoshone approximated \$25,000. A Chilean mill is being installed and will be running in a few days.—The Morgan, Stofelt & Cook lease on the Blue Jacket property at Round Mountain has a pile of \$100 ore on the dump ready for a mill-run.—The Tonopah Extension Mining Co. is to issue 5-year bonds to raise \$150,000 necessary for the construction of a mill on the property.—Sinking has been resumed in the Belmont shaft of the Tonopah-Belmont.—The foundation for a 12-drill compressor has been completed at the Tonopah Mining Co.'s property.—The Jolly Jane lease at Pioneer has installed a 20-hp. electric hoist.

WHITE PINE COUNTY.

The Brilliant shaft of the Ely Consolidated Copper Co. had to be abandoned recently owing to the heavy flow of water. S. F. Snyder is superintendent.—The drill-hole on the Clipper claim of the Ely Central has caved for over 100 ft. and will have to be abandoned. A shaft is to be started on this claim sometime soon.

NEW MEXICO.

GRANT COUNTY.

The Chemung Copper Co. has levied an assessment of \$1 per share. The mine is opened to the 800-ft. level, showing orebodies that assay from 3 to 4% copper. A survey for a railroad to the mine is being completed.

SOCORRO COUNTY.

A 225-hp. electric hoist has been installed at the Socorro Mines Co.'s Little Fannie mine at Mogollon. At the new mill 30 stamps are in place and 10 can be added when the mine output warrants it. The mill will be started in the early part of August. James A. Force is manager.

TAOS COUNTY.

The Lillian Mining Co., operating a lease on the Lillian mine, seven miles north of Red river, is developing a vein that mills between \$15 and \$20 per ton. There is a 10-stamp mill on the property that will soon be started.

OREGON.

BAKER COUNTY.

The Double Eagle group near Greenhorn has been bonded and is to be opened shortly.—W. A. Gillian and associates have commenced work on their Three Links property. Two veins, 18 in. and 3 ft. wide, have been opened by surface cuts and a short adit. The company will sink and cross-cut the vein at a depth of 100 feet.

GRANT COUNTY.

The Anniversary Gold Mining Co. has been incorporated to open the Anniversary group in the Granite mining district. A drift has been driven 575 ft. on the vein and a 275-ft. raise put through to the surface. The vein for this distance averaged 18 in. wide and assayed from \$8 to \$20 per ton. Frank Pence is in charge of the work.—C. E. Curry is having lumber hauled to the Trail creek placers for flumes and sluice-boxes.

UTAH.

JUAB COUNTY.

In the main adit of the Blain group in the west end of the Tintic district a vein has been cut that assays about 50% lead and 8 oz. silver per ton, with some gold. A lower adit is being driven to drain the property, as a winze on the vein struck a heavy flow of water. B. F. Fleimer is in charge of the work.—At the Eureka Lily the shaft is to be sunk to the 500-ft. level. On the 200 and 300-ft. levels

some excellent ore has been opened.—A double-compartment shaft is being sunk on the Selma group in North Tintic.—An electric hoist is to be installed at the Tintic Empire, at Tintic, to sink to the 200-ft. level. Al. Moore is in charge of the work.—Two cross-cuts are being run on the McKinley property in search of the orebody.—The Grand Central has opened its orebody on the 2000-ft. level west of the shaft. A cross-cut for this shoot has also been started from the 1800-ft. level.—A 25-ton shipment from the Beatrice mine averaged \$21 per ton. P. J. Daly is in charge of the work.—The July shipments of the East Tintic Development Co. will amount to four carloads. The ore brings a premium at the smelters on account of its high percentage of lead.—On July 10 the Sioux Consolidated declared a dividend of 7c. per share, and the Colorado and Iron Blossom companies declared dividends of 8c. per share each.

SALT LAKE COUNTY.

A double-compartment shaft is being sunk on the property of the North Bingham Mining Co. in Barney's canyon. A recent shipment to the smelter assayed \$32 gold per ton.—The Bingham Mines Co. has closed a contract with the Yampo Smelting Co. to deliver from 100 to 150 tons of copper-iron ore to the smelter from the Commercial mine. The company is shipping lead-silver ore from the Dalton and Lark mines to the smelter of the American Smelting & Refining Co. Imer Pett is manager.—The thirteenth unit in the mill of the Boston Consolidated has been started and the company is handling between 2700 and 3000 tons of ore per day. A. J. Bettles is mill manager.—The Utah Consolidated Mining Co. has let a contract for the construction of an aerial tram from the mine in Carr Fork canyon over the West mountain range into Pine canyon to the Trenton Iron Works.

TOOELE COUNTY.

The report of the Cliff Mining Co. shows a profit for the past fiscal year of \$50,000. The mine shipped only a portion of the time, owing to the low price of silver and lead, but spent a large portion of the time in development work. In the upper and main adits and on the lower level 120 ft. below the main adit the shoot has been opened more than 400 ft. Grant Snyder is manager.

WASHINGTON.

FERRY COUNTY.

The Republic mine in the Republic district shipped its fourth 50-ton car of sacked ore to the smelter. This ore runs above \$150 per ton.

OKANOGAN COUNTY.

Charles H. Brooks, of New York, has bought the Gehard group of claims on Palmer mountain.

STEVENS COUNTY.

Howland Bancroft, of the U. S. Geological Survey, is in the Chewelah mineral district to make a detailed survey of the district for the Government.—The Evergreen Mining & Development Co., near Colville, will commence shipping in August. William P. White is secretary.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The McKinley group of copper claims in Franklin camp, 40 miles north of Grand Forks, in the Phoenix district, has been bonded by G. A. McLeod and associates, of Spokane. The ore is copper and gold and assays between \$12 and \$40 per ton.—A compressor and drill has been added to the equipment of the Greenwood-Phoenix property. The adit is now in 160 ft.—H. R. Robbins, of Seattle, has been appointed mining director of the Apex group in the Similkameen district and has moved his residence to the mine.—The Blue Bird Mining Co., through Lyman Carter, has purchased the lease of Whitford & Jenkins and will sink a double-compartment shaft on the Blue Bird mine. Carbonate ore has been opened which assayed as high as \$80 per ton. About 40 tons of this ore has been shipped to date this year, and there is a carload now at the mine ready for shipment.

Placer gold has just been found on Seymour creek near Vancouver. It is claimed by the prospectors who have located ground on the creek that gravel will assay from

\$150 to \$200 per ton. Panning the sand the prospectors obtain 10c. to 20c. per pan, and it is asserted that gold at 4c. per pan will pay.—Another rich strike is reported from Portland Canal on the property of the Stewart Mining & Development Co. The ore assays \$24 to \$34 in a vein averaging 6 ft. and traceable for over 2000 feet.

Vancouver, July 10.

A new diamond-drill has been started to prospect the ground in the Ymir mine in East Kootenay.—The Highland mine near Ainsworth has been purchased by J. S. Airheart from W. J. Wilson.—A tramway is being built at the Aurora mine, near Moyie, to carry the ore from the tunnel down to the lake for shipment.—A trial lot from the Gold Note mine, a short distance west of the Granite Poorman, has been shipped to the Trail smelter.—A payment of \$15,500 was made on the Kootenay Belle, Sheep Creek, by the purchasers, J. L. Warner, F. M. Black, and F. E. Morrison. This is the third payment to the owners, Thomas Bennett and H. M. Billings, of Nelson.

ONTARIO.

A 75-ft. drift on the 100-ft. level of the Temskaming & Hudson Bay mine has opened a 3-in. shoot carrying 2500 oz. of silver. The company is now running 700 tons of second-grade ore that has been stored on the dump through the concentrator with satisfactory results.—Surface work on the Lawson mine has opened a cross-vein from the Silver Sidewalk that assays high in silver. It has been stripped for 200 ft.—The report for the Buffalo Mines, Ltd., for the past fiscal year shows 931,991 oz. silver and 54,794 lb. of cobalt mined that netted a profit of \$204,289. The cyanide plant is nearly completed and the mill is to be enlarged to handle 200 tons of ore per day. Thomas R. Jones is superintendent.—A 20-stamp mill is to be erected at the Nova Scotia mine. D. M. Steindler is president of the company.—A 6-in. vein carrying smaltite and native silver has been cut at the 75-ft. level of the Otisse mine at Silver lake.

MEXICO.

CHIHUAHUA.

The celebrated Mexican silver mines, near Parral, formerly owned by Pedro Alvarado, who once offered to pay off the Mexican national debt with profits taken from his mines, have been purchased by an American syndicate. A corporation called the Alvarado Consolidated Mines Co. has been formed to operate the mines. Shares of the company are now being offered for sale in New York and Boston. The par value of the shares is \$10. They are offered at \$5. Elaborate prospectuses have been circulated. They state that the company desires to sell 200,000 shares to raise money for a cyanide plant.

COAHUILA.

The Coahuila Mining & Smelting Co. has opened a body of ore on the Alberto property about 300 ft. from the present working that assays about 2 kg. silver per ton. W. A. Williams is manager.

JALISCO.

Patrick Clark, of Spokane, has sold his interest in the Magistral-Ameca mines, near Guadalajara, to his partners, who will continue the development of the copper property.

SONORA.

The Candelero Mining Co. is building a mill and cyanide plant on their property near La Barranca. S. Ben. Smith is superintendent.

ZACATECAS.

A new cyanide plant is being erected in the city of Zacatecas for the custom treatment of the low-grade ores of that district. Marcelino Velasco y Peña, the engineer who has made the estimates and plans for the plant, calculates that the extraction and treatment costs will approximate \$5 per ton. A 50-ton unit will be first put in operation, and others added as the needs of the plant increase. The State Government has taken an active interest in the project and aided it with a subscription of \$30,000 for 1200 shares of the company's stock.

TASMANIA.

The Oona Mines, Ltd., has started smelting at its mines near Zeehan. The work is proceeding smoothly.

Special Correspondence.

LONDON.

Mining Tax.—Burma Ruby.—Mond Nickel.—Aluminum.—Institution of Mining Electrical Engineers.—Exploration Company.

In a recent letter I referred to the proposition for the taxation of unmined minerals. The purpose is to make the landowner pay one half-penny per pound per annum on the value given to the land for its mineral contents. This measure was aimed at the coal and iron lords, and the difficult matter of assessing is to be left in the hands of officials of the tax office with no provision for appeal to the courts. The opposition is naturally strenuous. The taxation of mineral values before they are won is a doubtful economic policy. Furthermore, the act does not define the word 'mineral'. The Government declines to provide this definition, saying that the intention is to use the word in its legal sense. When it is pointed out that the judges have given a variety of different definitions of the word, the spokesman says that the matter of interpretation will be left to the tax officials. In this column about a year ago I gave an account of the dispute between a railway and a china clay company as to the meaning of the word 'mineral'. It was then argued that china clay was not a mineral, because it was a mixture, being the result of the decomposition of a rock. This was the narrow mineralogical meaning of the word, but as the action was being taken under an act which specifically included granite, slate, and coal in its definition of mineral, it was obvious that china clay also must be included. In all legal decisions a mineral has been held to be some substance of the earth's body which imparts to the land a value apart from its surface value, and the only difference in the various decisions relates to such substances as brick earths, brick clays, gravel, and sand. There is also some doubt as to where the line must be drawn in connection with chalk. If the decision, as to what is or is not a mineral under the taxation act, be placed solely in the hands of the tax officials, everything will be classed as mineral, because it is to the interest of the officials to catch everything. However, the act has not yet passed into law; perhaps it never will.

The market for precious stones continues to be in a depressed condition, as may be gathered from the position of the Burma Ruby Mines, Ltd. These mines belong to an English company which was floated by the Rothschilds 20 years ago. The history of the company has been somewhat melancholy, because of losses of capital, floods, bad times, and high royalties. The year which ended February 29 last was a disastrous one financially, £8242 having been lost. The mines have been shut down partly and only day work has been attempted. The total amount of ruby earth washed during the year was 1,071,166 trucks, compared with 2,033,666 trucks in the previous year, and the average cost per truck increased from 7s. 6d. to 7s. 9d. The depression in the market for colored stones seriously affects their sale in London, though the local demand in India continues fair. The only policy for the company to adopt is to husband their resources, and in the meantime to obtain a remission of arrears of rent and current rent due to the Government. The construction of the drainage tunnel which was commenced three years ago was completed last summer, and has proved highly efficacious in clearing away the water from the lower levels after the floods which are common in that district.

The Mond Nickel Co., Ltd., became an established commercial success a year or two ago, and the dividends paid are now steady and permanent. During the year which ended April 30 last the profits were £141,242, as compared with £137,098 during the year previous. The rate of dividend is the same as in the previous year, being 7% on preference and 15% on the ordinary shares. Each year £22,800 went to the holders of the deferred shares. The amount placed to reserve was £20,000, as compared with £25,000 the year before. During the year £250,000 of additional capital

was raised by the issue of 50,000 new preference shares of £5 each, for the purpose of completing the hydro-electric power station on the Vermilion river and electrifying the mining and smelting plant at the Victoria mines. Both of these works are now completed, and will effect considerable economies.

The position of the English companies producing aluminum continues to be a very precarious one. It is only a few months ago that I recorded the re-organization of the Aluminum Corporation which was formed as recently as two years ago. This failure was not altogether unexpected, as the company had no supplies of raw material. The other company, the British Aluminum Co., when I wrote my last notes on the subject of the production of aluminum in this country, seemed to have passed through its troubles and arrived at a period when shareholders might expect to receive some return. It is decidedly disconcerting, therefore, to find that in the Chancery Court this week application was made for a receiver and manager on behalf of the debenture holders. It appears that the company has bills maturing on July 1, amounting to £100,000, and there is also a substantial overdraft. The company was originally formed in 1894 and started hydro-electric works in Scotland, at the celebrated Fall of Foyers. It also acquired supplies of bauxite in the north of Ireland. For many years financial mismanagement and technical difficulties involved the company in all sorts of difficulties. It became necessary on several occasions to raise new capital and to re-organize. Recently large sums of money were raised for the construction of new works at Loch Leven, near Ben Nevis, in Argyllshire, since the capacity of the Foyers plant was too small. The new plant is now practically completed and is an excellent specimen of modern electro-metallurgical engineering. The great drop in price of metal appears to be the immediate cause of the present financial difficulty. Last year I referred to this and pointed out that when the price had been reduced to that of copper, the future use of aluminum should be greatly extended. This is borne out by the experience of the British Aluminum Co., but unfortunately the drop in the price has hit them more than the increased demand has done good. Until the Loch Leven works are in full swing it is impossible for them to even matters. The receivership will strengthen the company's position and enable it to weather the storm. It may be of interest to note that the debenture holders who petitioned the court for the appointment of a receiver were the executors of the late Charles Morrison, the millionaire, who was the nearest approach to your late Russell Sage that has been produced in this country.

Of the formation of new technical societies there is no end. The latest formed in England is the Institution of Mining Electrical Engineers, and its object is to get together the engineers who are in charge of electrical plants at mines. The membership is being confined for the present to engineers in the United Kingdom, but it is hoped eventually to cover the whole world. There are to be branch sections in each mining district, and local as well as central meetings will be held. The qualifications are that the applicant must have been in charge of an electrical installation of a certain magnitude in a mine for so many years, or be a member of the Institution of Electrical Engineers. The Institution originated from the efforts of J. Williams, of Whitehaven, Cumberland, and William Maurice, of the Hucknall Colliery, Nottingham. As I have often remarked in these columns, the application of electricity in mines requires close study, for there have been many bad failures in connection with it in England, and the formation of a society which will bring together those who are responsible for the success of such plant should serve a useful purpose.

It has always been the policy of the Mexican mines controlled by the Exploration company to publish what may be called a forecast of the regular yearly report. Such information has just been given out by the El Oro Mining & Railway Co., Ltd., and the Mexico Mines of El Oro, Ltd., with regard to the results for the year to end June 30. For the Mexico Mines of El Oro, the estimated profit is £152,143, out of which £112,500 is being distributed as dividend and £25,000 devoted to writing off expenditure on the

mill. The El Oro company's profits for the same period are estimated at £207,000, of which £172,125 is to be distributed as dividend, and £33,270 written off all expenditure on improvements incurred during the year.

MEXICO.

Zacatecas Custom Plant.—Cerro de Proano at Fresnillo.—Railroad Connections.—Oil Development.—La Blanca, Pachuca.

In a recent letter I spoke of the new cyanide plant in contemplation of Zacatecas by Marcelina Velasco y Peña, and stated that though of sufficient size to make commercial runs, it would be solely a testing plant. It now appears that the plans of Sr. Velasco y Peña and his associates are to construct a 50-ton mill and run it as both a testing and a custom plant, making experimental runs on ores or buying ores outright, as their clients may desire. It is believed that 350-gm. silver ore may be handled without loss, and that 600-gm. ore may yield a nice profit. It is to be capitalized at \$150,000, with 6000 shares of \$25 each, and the hope is that it may be pushed to rapid completion, for it is certain to have a stimulating effect on mining about Zacatecas. At Fresnillo, in the State of Zacatecas, and but a short distance above the city of that name, on the Mexican Central railroad, Robert S. Towne has taken an option on the old workings of the Cerro de Proano, which have yielded silver as far back as 1558. In the time of the option—one year—he will make a thorough test and examination of the ores and workings, as to extent, tonnage, and economical treatment. As Mr. Towne has for many years been leaching the old Fresnillo tailing-dumps from these same workings, first by hyposulphite and more recently by cyanide, he is thoroughly familiar with the work and ore at hand, and is excellently equipped for carrying out his experiments.

One of the most important reports that has reached Mexico recently, in addition to the contemplated new work in railroad building by the Cananea Consolidated Copper Co., and of the Mexican Northwestern railway, is that the Kansas City, Mexico & Orient railway has entered into some kind of a traffic arrangement with the Chicago & Alton, whereby, with the latter and its Eastern connections by the Chesapeake & Ohio to Old Point Comfort, the K. C., M. & O. may, when completed to Topolobampo bay, have a through traffic arrangement from the Atlantic to the Pacific that will be some 800 miles shorter than any other, and will mean much for the west coast of Mexico. If there is anything in this report, it is expected that the Chicago & Alton may in some indirect way assist the K. C., M. & O. (or Orient, as it is called) financially in the completion of its line. Of great importance to the southern part of Mexico is the concession recently granted for a 150-km. railroad from Tezuitlán to the new gulf port of Nautla, running through the States of Puebla and Vera Cruz, with branch lines to the oilfields of Fubero and Dos Bocas. It is stated that there is about \$5,000,000 behind the project, and an excellent future is predicted for it, as connection may be made at Tezuitlán with the Inter-oceanic, and thereby a shorter line, between Mexico City and the Mexican gulf than any existing, be created. As the Tampico and Vera Cruz wharfage facilities are overwhelmed, it is believed there is room for a great deal of business for the new port, and for the new road. At the oilfields of Fubero work by S. Pearson & Son on the railroad, tanks, and 6-in. pipeline is progressing, the organization of the Cia. Mexicana de Petróleo 'El Aguila', S. A., to take over the greater part of the Pearson holdings having a dilatory effect on these contracts. It is believed the pipe-line of 91 km. may be delivering oil by September. By this contract the Oil Fields of Mexico Co. turns its entire product over to the Pearsons at a certain rate per barrel, to be agreed on each year according to the market, while S. Pearson & Son obligate themselves to construct a narrow-gauge railroad of 83 km. and a 6 in. pipe-line of 91 km. from Fubero to Tuxpám, with a tank at each terminus, all at an expenditure of from \$1,000,000 to \$1,250,000, which is to be paid for, with interest at 5%, by the Oil Fields of Mexico Co., at the rate of

10c. per barrel of oil delivered to S. Pearson & Son, who contract to receive a minimum of 2000 bbl. daily, the pipe-line having a capacity of 12,000. During the construction of the pipe-line and railroad no further development will be made of the oilfields, but as the existing wells have a productive capacity of 20,000 bbl. per day there is no great present need for additional boring.

Report has it that E. H. Harriman, whose work in the Mexican oilfields is being closely watched, has struck oil at El Jobo, near Tuxpám, at a depth of 2900 ft., the oil having an asphalt base similar to that of S. Pearson & Son's farther up the Tuxpám river, and drilling will be started immediately on a second well. Many are of the opinion that the Standard Oil Co. is coming into the Mexican field to assist the Waters-Pierce Oil Co. in the competition which it is meeting from the antagonistic S. Pearson & Son, or

San Rafael Mill, Pachuca.

the Compañía Mexicana de Petróleo 'El Aguila' S. A. The latter has a strong Mexican backing.

Ever since the successful promotion and sale by the MacDonald Bros. of the Real del Monte of Pachuca, endeavors have been made to carry through a like deal with its near neighbor, La Blanca. Several options have been taken, only to fall through, though one was said to be to John B. Farish, of Denver. Now it is stated that another option has been given to Hugh Rose for Cortlandt E. Palmer, representing New York capital, and John Hays Hammond, backed by London investors. A complete examination for those interested has been made by F. W. Royer. The figures at which the option is held are not made public, but they are thought to be well up in the millions. If carried through it means more large cyanide plants for Pachuca.

GUADALAJARA, MEXICO.

Cinco Minas Sold.—Magistral Copper.—Casados Mine.—Sombretete.—Guadalupe de los Reyes.—San Geronimo.—Government Subsidizes Shaft-Sinking.

John B. Farish, of Denver, has made an examination of the Cinco Minas, famous *antiguas* in the Hostotipaquillo district of Jalisco, and as a result of his report the deal for the purchase of the mines by the Marcus Daly interests for \$530,000 will be carried out. Mrs. Daly, head of the Daly estate, has made another payment on the purchase price, and has advanced considerable money for further development and for mining machinery. The Cinco Minas deal has been held up since last April, when Ernest A. Wiltsee, a New York mining engineer, sent to Mexico by the Daly estate, made an unfavorable report on the properties, recommending that the purchase be not made. In his report Mr. Farish reverses the Wiltsee finding, and sustains H. E. Crawford, the New York engineer who interested the Daly estate in the mines, predicting even a more important mining enterprise than pictured by Mr. Crawford. The new development in the mines, which has been in progress since last fall, has resulted in finding considerable rich ore and in opening big bodies of milling ore below the old workings, and in disclosing virgin ground at the same levels as previously worked. A five-stamp experimental plant will be erected at the properties, and later a 250-ton

plant will be built. The Cinco Minas have a recorded production of many millions. Patrick Clark, of Spokane, Washington, is no longer connected with the Magistral copper enterprise in the Ameca district of Jalisco. His interests have been purchased by James P. Harvey, H. L. Percy, and Fred M. Lyons, all of Los Angeles, California, and they are now in control. The Magistral-Ameca Copper Co., capital \$1,500,000, has just been organized in the United States to operate the properties, and of this company Mr. Percy is president, Mr. Lyons vice-president, and Mr. Harvey general manager. The transfer of the Clark holdings resulted from a disagreement between the Spokane man and his three partners over the distribution of stock and the management of the proposed American company. Clark and the Los Angeles men arranged an option on the Magistral mines two years ago, and last fall purchased them for \$100,000, organizing a Mexican holding company to receive titles and carry on the work. The ore now in sight in the mines is estimated to have a value of \$1,200,000, and a 150-ton reverberatory smelter will be erected at the properties within the next few months. The Sombrerete Mining Co., of which Robert S. Towne is the head, is planning the installation of a big hydro-electric plant on the Durango river in the Sombrerete district of Zacatecas, and the transmission of electric current to the mines and reduction plants in the Sombrerete, Nieves, and Chalchihuites districts. Hydraulic surveys have shown that from 8000 to 10,000 hp. can be generated. The Towne interests are extensive in the three districts, and electric power would give great impetus to mining and milling in that portion of Zacatecas. Considerable rich ore is being taken out of the Casados mines in the Hostotipaquillo district of Jalisco, and from two to three carloads are shipped to the smelter monthly. The returns range from \$3000 to \$7000 per car. The milling ore opened in the Casados warrants the erection of a reduction plant, and one of 100 tons capacity will be built during the next year. The mines are owned by the Consolidated Mining Co., W. R. Ramsdell, president. The Guadalupe de los Reyes Mining Co., one of the most important mining concerns in the State of Sinaloa, has practically decided to build a power plant on the line of the Southern Pacific extension and to transmit current to its mines and reduction plant, a distance of 68 kilometres. The company is now generating electricity by steam at the properties, and is standing a heavy fuel charge, which can be greatly reduced by having a power plant on the railroad. The 30-ton mill and concentrators of the Lawson Development Co., on the San Gerónimo hacienda in the Mascota district of Jalisco have been placed in commission, and are operating on ores from the company's mines and from other Mascota properties. More than a year ago the Lawson company, which is headed by Thomas W. Lawson, and managed by Frank W. Page, made plans for extensive mining development in the Mascota district, and secured options to purchase several mines. However, the plans were not carried out, and the options lapsed, but another effort may be made soon to put at least some of the plans into effect. The Makeever transportation tunnel of the big El Favor mine in Hostotipaquillo district of Jalisco has cut the main vein of the property at a depth of 750 ft. The vein is 55 ft. wide where cut, and the greater part of it is milling ore. All the levels of the mine are being connected with the Makeever tunnel, and all ore will be sent through it to the 100-ton mill now building. Work has been resumed on the Nueva Luz shaft of the Mineral Development Co. in the Guanajuato district of Guanajuato, and the present depth is 1175 ft. The company is now receiving from the Mexican Government a subsidy of \$150 per metre, the subsidy having become effective when a depth of 500 metres (1640 ft.) was reached. The shaft will extend into the earth 3000 ft., and at that depth a cross-cut will be run to tap the Veta Madre, or mother lode, of the Guanajuato district. The Government is interested for the reason that the shaft will serve to prove the Guanajuato district at great depth. The Guanajuato Consolidated Mining & Milling Co. has installed a filter at its cyanide plant in the Guanajuato district, and announces a saving of \$18,000 per month as a result.

WASHINGTON.

Senate Tariff Bill Passed.—Experiment Stations.—Alaska.

The tariff bill finally has passed the Senate. The conferees are now holding protracted sittings in hope of harmonizing the downward revision of the House with the upward revision of the Senate. When they get through, the action of the Senate, with probably few minor exceptions, will be the law, for the Senate always has its own way in matters of serious legislation. The House likes to play the political game to that large gallery, the American people, at the same time believing that what the people often demand loudly is not good for them, and that the Senate can be trusted to eliminate the hurrah things that have crept into the bill. N. B. Aldrich, Senator from Rhode Island, and chairman of the Finance Committee, evidently holds that the people in their clamor for downward revision were wrong, for practically every schedule he has offered has lost sight of this important issue of the last campaign. The Senator from the little State has been an ideal person to carry out such a program. His constituency is such that he is assured a life position in the Senate. No storms of popular indignation ever beat about his head. Rhode Island is proud of its big man who knows how to keep his head under the most trying circumstances, who knows how to forget his personal feelings in the great task of making a new tariff. Mr. Aldrich has been bitterly assailed at times, both by Democrats and Republicans, because of his firm stand for a high tariff, but in the midst of the most scathing denouncement of his dictatorial methods, and they were dictatorial, his ears have been deaf to the personal comment, and have only heard the suggestions that went to carry out his original program. There is discussion throughout the country as to whether Mr. Taft will sign the tariff bill. There is no doubt here but that the bill will become a law. The argument is being advanced that if the present prosperity continues and increases, the people will forget the downward revision promise in the good times; if the business of the country gets bad, the Republican party will be defeated in the next election and would be defeated whether the tariff bill was high or low.

The last day of the hearing on the tariff bill saw the independent oil men of the country gain a slight victory. Crude petroleum remains on the free list, but an amendment has been added which provides a countervailing duty. The smelter-fume nuisance was attacked from a new point when arsenic was placed upon the dutiable list. The effect of the Senate provision for a tariff of 60c. per ton on screened coal and 15c. on screenings is being much discussed. On the one hand it is urged that this is necessary to protect the coal miners of Utah, Washington, and Wyoming against Canadian competition on the Pacific Coast, and to hold the markets of New England for West Virginia and other Eastern bituminous producing States. It is pointed out, however, that despite present prices of \$1 to \$1.65 per ton less for Canadian coal than for that from the Virginias, the high quality of the latter enables it to practically control the market. It is idle to guess as to results till the Conference Committee decides what the tariff is, but the fact seems to be that S. B. Elkins and his fellow owners of West Virginia coal mines want as high a price for their coal as they can get, and that Mr. Aldrich has made this concession a matter of trade for votes. An interesting provision of the bill is a drawback to be paid when the imported coal is used on steamers of American register engaged in foreign or coastwise traffic.

Thomas H. Carter, Senator from Montana, has introduced a bill in the Senate to establish 'The Glacier National Park', in the Rocky Mountains south of the international boundary and in the State of Montana. The same Senator also introduced a bill providing for the appointment of an inspector of mines for the District of Alaska. Mr. Carter also has a bill to establish engineering experiment stations at land grant colleges. Each is to be entitled to \$30,000 yearly. The report of the Geological Survey on Alaska for 1908 has just been issued as Bulletin 379.

DAWSON, YUKON TERRITORY.

Summer Work. — Yukon Gold. — Quartz Mining. — White Horse. — Caribou Crossing — Windy Arm Mines. — Atlin.

Summer is here, and the profusion of roses and fresh vegetables emphasizes the fact. Only the newcomers who step off the steamers with heavy blanket rolls and wearing winter clothing, remind us that we are in the Far North. There are many idle men now; some are being fed by the city government. Aside from the work of the Yukon Gold Co., not much is being done near Dawson this season. That big company is working at high pressure, trying to make the most of the present season. All their dredges are in operation and a good season's return is expected. Quartz mining is attracting some attention, and indeed certain of the veins look promising. One stamp-mill is being erected, but the real need is for a satisfactory dry process. Any form of wet crushing and concentration is bound to fail, since in the winter the machinery would inevitably freeze. The roads near Dawson are in excellent shape, and this greatly facilitates such work as is being done.

At White Horse, Greenough Bros. of Spokane have taken options on a number of copper claims, among which are the Pueblo, belonging to Byron White, and the Arctic Chief group, partly developed by W. J. Elmendorf. Plans are being made for important work.

The White Pass & Yukon railroad runs along the east bank of Lake Bennett, at the foot of which is Caribou Crossing, a narrow channel that forms the outlet of Lake Bennett into Lake Tagish. An arm of the latter extends southerly a distance of 50 miles, thus making a peninsula 20 miles wide between Lake Bennett on the west and Lake Tagish on the east. The northern portion of this peninsula is indented by Windy Arm, which has a length of 10 to 12 miles. The projection of country lying between Windy Arm and Lake Bennett, about 10 miles in width, is officially designated Windy Arm district. On the Windy Arm side is the town of Conrad, which is about 12 miles by boat from the railroad at Caribou Crossing. Near this place is the Venus mine, belonging to the Yukon District Gold Mines Development Co., in which Col. J. H. Conrad, E. E. Harvey, and their associates are interested. The property is 1750 ft. from the wharf, at an altitude of 1000 ft. above the lake level. It consists of a well-defined vein in a porphyritic country, which is opened by cross-cuts from the mountain slope. The vein has an average width of 3 ft., on which there is, approximately, 1000 ft. of driving in ore. The gangue material is quartz, carrying in the main an argenterous galena, accompanied by some arsenopyrite and chalcopyrite; in the higher workings are lead carbonate and malachite in small quantity. All these ores contain some gold. It is said the silver, lead, and gold have a gross value of \$25 per ton. No. 1 cross-cut goes in 60 ft., where it strikes the vein, on which there are 170 ft. of driving at this level. No. 2 cross-cut intersects the vein 496 ft. from the portal and 272 ft. below No. 1 on the dip of the vein. On this level there is 400 ft. of driving each way from the cross-cut. Besides this, raises have been made and stopes opened at various places. Most of this work was done under direction of W. S. Whitman, who states that 3500 tons of ore have been stoped out above this level. They operate air-drills, the air-compressor being driven by water in the summer season. An aerial tramway conveys the ore from the mine to the mill, the latter situated near the wharf. The mill was operated last season, but has not been started this season, and it is said some changes are contemplated. The equipment comprises a crusher, two sets of rolls, jigs, Huntington mill, Wilfley tables, and vanners. R. R. Hornor is superintendent, and has a force of miners developing the property.

The Big Thing property, belonging to the British Yukon Gold Mining Co., is situated on the Lake Bennett slope of Windy Arm district, six miles from Caribou Crossing. It consists of a series of parallel lodes in a body of granite that lies between porphyry and limestone. The company's development is thus far confined mostly to one of these lodes, which has a gangue of quartz and altered granite. It has a dip of 30°, and the plan of development is to sink

shafts, or inclines, on the lode and run drifts from them. There are several hundred feet of work of this character. The width of the lode is not definitely fixed, as the ore gradually fades into the country rock. The principal metal is gold, though there is a good deal of silver, all carried in quartz and iron pyrite, accompanied by none of the other base metals. The ore is said to run over \$20 per ton. The matter of erecting an aerial tramway, 3¾ miles long, to carry the ore to the railroad, is being considered. As the ore is believed to be adaptable to cyanidation it may be decided to treat it at the mine. Those responsible for the operations and results are J. H. Conrad, H. W. Vance, and W. S. Whitman.

Caribou Crossing is the place from which the steamboat *Gleaner* makes semi-weekly trips to Atlin, by way of Tagish lake and Taku inlet, there being a portage railroad from the latter to Lake Atlin.

BUTTE, MONTANA.

Amalgamated Changes. — Ray Consolidated Sale. — North Butte. — Pittsburg & Montana Foreclosure.

The Butte mining companies, especially those of the Amalgamated Copper Co., are still trying to reduce costs. They are now experimenting for the purpose of substituting electric power for steam in transportation, and Nordberg engines are proposed. John D. Ryan, president of the Amalgamated Copper Co., says the change will reduce the cost of production fully one-third of a cent per pound. Mr. Ryan has great faith in the future of the Butte mines and in the future of the copper industry. He is not at all disturbed by the increasing production of the metal, and predicts still greater production and higher prices for copper. He calls attention to the fact that during the year ending July 1 the Amalgamated company paid \$6,400,000 in freight charges, \$15,000,000 in wages, and \$10,000,000 for supplies. During the same period the Butte district produced 325,000,000 lb. of copper. Mr. Ryan has declined to discuss the rumors that plans are on foot to take all of the Cole-Ryan companies into the Amalgamated company. It is a well known fact that Mr. Ryan and William Rockefeller have always favored a policy of expansion. H. H. Rogers, it is understood, was against that plan. His idea prevailed and the North Butte, Butte Coalition, Greene-Cananea, etc., were organized as separate units. It is predicted that when the time is opportune a consolidation will be effected and that the Guggenheims and Morgans will be found to be working in harmony with the new Standard Oil copper management. George W. Perkins, on his way to visit the Guggenheim and Morgan copper fields in Alaska, stopped at Butte as the guest of Mr. Ryan.

R. D. Grant and Philip Wiseman, formerly of Butte, but now associated with the American Development Co., at Los Angeles, have sold their interest in the Ray Consolidated Co., to Bernard M. Baruch, representing the Guggenheims, for \$1,100,000. Grant and Wiseman promoted the Ray company, whose property is situated in Arizona. W. D. Thornton, president of the Green Consolidated Co., has been in Butte for several weeks, in consultation with Mr. Ryan, president of the Amalgamated company. The policy of the North Butte officers would seem to strengthen the general fear of stockholders and reports from the mine that the property is gradually deteriorating, or at least is not keeping up its former record. Strict orders have been issued that no information of any character shall be given out in Butte.

The property of the Pittsburg & Montana Copper Co. is in the hands of two receivers, R. T. Rossell having been appointed at Pittsburg and Oscar Rohn at Butte. The latter is manager of the company, and under orders of Judge Hunt, of the Federal Court, he will continue operations pending mortgage foreclosure proceedings. The foreclosure is part of the plan to turn the Pittsburg & Montana over to the East Butte Copper Mining Co. The foreclosure suit will be pushed to conclusion as rapidly as possible, and it is understood that there will be no opposition to the proceeding.

NEW YORK.

Greene-Cananea.—Zinc Output.—Boston & Goldenville.—Birkinbine's Report on Iron Ore Reserves.

The Greene-Cananea mine has now been operated by the new management for a little over a year. In this period the mining operations have been greatly extended, and the smelting plant has been re-arranged. While these changes were being carried on it was impossible to run the smelter at its full capacity. The smelter yielded 42,000,000 lb. copper, 957,770 oz. silver, and 6178 oz. gold in the period reviewed. The mine is now in first-class condition, and L. D. Ricketts, the manager, reports that the smelter is giving satisfaction. During the current year larger returns are expected, as it is proposed to blow in the whole eight furnaces shortly. In the past year only four were operated. The full capacity of the smelter is about 6,500,000 lb. of copper per month.

Notwithstanding that the markets for metallic zinc and lead are heavy, the output of the Missouri and Oklahoma zinc mines is increasing. The total shipments of ore from the mines of both States for the past 27 weeks were valued at \$7,000,000. The shipments during the last week in June contained 11,310,400 lb. zinc as blende, valued at \$244,247; 1,626,270 lb. lead, valued at \$46,498; 1,047,270 lb. calamine, valued at \$11,562. The total value of the week's yield was \$302,307. Many new mines are being developed, and prospects indicate a still larger output. An American company has acquired the Goldenville gold mines at Goldenville, Nova Scotia, and is preparing to develop them extensively. The company is known as the Boston & Goldenville Mining Co. Its main office is in Boston. According to the mine manager's recent reports, development is proceeding satisfactorily. Shaft-sinking and diamond-drilling are being carried on.

The statement has been frequently made to the effect that the United States Steel Corporation owns 85% of the iron ore in this country. This has brought forth a remarkable reply from Joseph G. Butler, Jr., of Youngstown, Ohio. Mr. Butler employed John Birkinbine to look into the matter, and he finds that the Steel Corporation owns 38½% of the available desirable ores, and but 3% of the whole. According to the figures of the United States Steel Corporation, the 'available' ores amount to 1,717,589,000 tons. Including all the iron ores of all kinds, amounting to 79,186,000,000 tons, and allowing that the United States Steel Corporation owns 2,322,434,000 tons, the actual percentage of iron ore in the United States owned by the United States Steel Corporation is 2.9% of the whole, instead of 85. The Corporation up to the present has no holdings whatever in the East, where on account of the electric concentrating process, the Lake Champlain and Adirondack district are rapidly forging to the front. Mr. Butler says he believes the output of these mines, together with the ore produced by the concentrating process in New Jersey, will in time equal the shipments from Lake Superior. The ores from the latter district are high in metallic iron, and for that reason are desirable and have the broader market. In 1907 the independent iron-ore producers mined and consumed 29,000,000 tons of ore, as compared with 22,000,000 tons consumed by the United States Steel Corporation. Mr. Butler predicts that within ten years, at least 10,000,000 tons of Cuban ores will be imported per annum and consumed on the Atlantic Coast. The deposits of iron-ore in Cuba are estimated at 600,000,000 tons. Mr. Birkinbine, in summing up his report on the iron ores of the East says: "It is very difficult to put an estimate on the quantity of unmined ore in the East, but a conservative estimate of the magnetite deposits alone would undoubtedly exceed 400,000,000 tons crude ore, with a present output of at least 2,500,000. This output is likely to be very largely augmented in the near future by the development of new properties and the increased output of existing deposits. Probably no other iron-ore section in this country has greater promise of development, for the reason that there are large areas of low-grade ores which have in the past laid dormant, but which can now be made available by magnetite concentration. As the Lake ores mined, owing to the increasing

demand, are each year growing leaner, and as no satisfactory method for their enrichment has as yet been discovered, the rich concentrated ores of the East are likely to be in increasing demand in the future for mixing with the Lake Superior ores, and thus raising the yield. Only one serious drawback stands in the way of a large development of these Eastern ore fields, and that is, being situated in close proximity to the seaboard, they will be peculiarly sensitive to the competition of cheaply mined foreign ores, especially as more labor will have to be employed in mining a sufficient amount of crude ore to produce a ton of concentrate and for milling same."

LOS ANGELES.

Union-Independent Producers Alliance.—New San Pedro Wharfage.—Palmer Gusher.

Events of large interest to the oil industry of California have been succeeding each other in quick order during the past three weeks. Following the announcement of the formation of the Producers Transportation Co., backed and financed largely by the Union Oil Co., came the still more important news of the alliance of the Union and Independent Producers agencies in a marketing contract. This alliance is to continue 10 years, the Union joining the agencies, putting its southern California properties into the Kern County agency, and its Santa Barbara, San Luis Obispo, and Fresno county properties into the Coalinga agency, reserving, however, all oil which is more valuable for refining than for fuel. The Independent Producers agencies appoint the Union Oil Co. their sole marketing agent for a period of 10 years, beginning February 1, 1910. The Union agrees to market all of the agencies' oil, make the collections and suffer all losses through bad accounts, for 10% of the net price of the oil at the well. The charges for the transportation of oil from all of the fields will be paid out of total gross receipts from transportation, making the net price received by the producer in the Kern River field the same as the net price at Coalinga or Santa Maria. Thus, while the cost of transporting oil from the Kern River district to the coast by the new pipe-line will be 22½c., and the cost from some of the Santa Barbara county fields will be 7c., the actual amount paid by the producers will be the same in both instances. The agencies agree to maintain their present production, so that the Union will be able to enter into contracts on a constant basis. Provision is made for an increased production on the part of the agencies. A board of arbitration, consisting of four members, two from the Union and one from each of the agencies, will have power to pass upon all matters of doubt concerning the provisions of the marketing agreement and to determine the action in any case not specifically provided for in the contract. W. L. Stewart and Danzell Stoney will represent the Union on this board, L. P. St. Clair the Kern County agency, and S. W. Morsehead the Coalinga agency. The importance of the combination outlined above will be realized when it is considered that of the approximate total of 160,000 bbl. of oil now produced daily in the State, 60,000 will be controlled by the Union-Independent Producers; this is 62% of the total fuel oil used in the State outside of that required by the railroads. Another move which will doubtless have far-reaching effect upon the marketing problem, is the acquirement by the Union Oil Co. of a controlling interest in the Outer Harbor Dock & Wharf Co. This company owns 156 acres of the San Pedro water-fronts, and expects to immediately spend \$1,000,000 in the development of wharfage facilities.

The famous Palmer gusher in the Cat Canyon field, east of Santa Maria was uncapped recently, and by actual measurement made slightly under 10,000 bbl. of oil in 24 hours. The production fluctuates somewhat, owing to variation in the gas pressure, but it will come close to averaging 10,000 bbl. per day continuously when left open. The oil issues from this well with a roaring sound, and has blackened the vegetation for 200 yards around. It is handled by the Union and Associated oil companies, each of which has a pipe-line running to the property from their main lines in the Santa Maria field.

BRITISH COLUMBIA.**Sheep Creek Mines.—Queen.—Nugget.—Kootenay Belle.**

Sheep Creek, in Nelson Mining division, is attracting more attention than any other gold-quartz camp in British Columbia. Though its regular production of gold is not yet large, there are in it two or three mines that are maintaining a steady output of gold-bearing ore from which profitable returns are being received, and several other properties are being prospected with promising results. The camp is easily reached from Salmo, and is distant about 30 miles from Nelson and 170 from Spokane. Mineral claims have been located on Sheep, Wolf, and Fawn creeks. That gold-bearing quartz occurs here has been known for years. R. G. McConnell and R. W. Brock in 1897 directed the attention of local prospectors to the occurrence of promising quartz veins. As a result, numerous quartz claims were staked, and a few were developed. Of the latter, the Yellowstone, on which a 10-stamp mill was erected; the Queen, and the Kootenay Belle, were worked with more or less success. Eventually the Yellowstone and Queen groups passed into the possession of Wm. Waldie, of Nelson, and the Kootenay Belle, after having been bonded to several others at different times, was acquired under lease and bond by men

**Mineral Resources of British Columbia.**

operating from Nelson, who during the latter part of last year milled nearly 2000 tons of ore in a 4-stamp mill, recovering gold to the value of about \$23,000 by amalgamation and \$14,000 from concentrates. The geology of the district, according to R. W. Brock, is as follows: "The veins at present being worked occur in a band of quartzites, slates, and schists, which extend northward from about Lost mountains across Sheep creek, at the forks of Sheep and Wolf creeks, and up the ridge between Sheep creek and Fawn creek. To the west is a wide band of crystalline limestone. Some granitic and aplitic dikes are intruded into the formation; also some basic mica dikes. The general strike of the rocks is about N.12°E., with a dip of 50° to the east. The veins are fissure veins cutting the formation, usually the quartzite."

The prominent properties of the camp are the Queen-Yellowstone, Nugget, Kootenay Belle, and Mother Lode. Besides these and other gold properties, there is the Emerald, which produces galena ore carrying 60% lead and a few ounces of silver. Last year's production at this mine was 426 tons, valued at about \$7000. The total production of Sheep Creek camp to date has been about \$800,000. The Queen vein is 6 to 11 ft. wide, probably averaging about 7 ft. It is regular and has unusually clean-cut walls. The ore is white milky quartz, with pyrite and pyrrhotite in about equal proportions. There is some galena, blende, and chal-

copyrite. These sulphides constitute about 8% of the ore. The value lies chiefly in the gold, more than 50% of which is saved on the plates. The main adit has been driven 600 ft. on the vein; there a shaft was sunk 200 ft., and from the bottom of this drifts have been run both ways. Ore from this lower level is being milled; its average value is \$12 to \$14. The 20-stamp mill is operated by water-power, also one Wilfley and three Overstrom tables, and two air-compressors—one a 10 and the other a 5-drill. Six Pelton wheels, 15 to 48-in., provide power.

The Nugget vein is also a quartz-filled fissure traversing the quartzite. It is as much as 14 ft. wide. The pay-streak shows high-grade ore, and is in places only a few inches wide, and in others several feet. Much of the vein material is oxidized quartz. The Nugget group of three claims is situated on Fawn creek, on the north side of the mountain which separates that creek from Sheep creek. The Mother Lode and several other groups are on the south side. The Nugget Gold Mines, Ltd., owns the Nugget group, on which there is a plant, including a 4-stamp mill, with boiler, engine, crusher, and two 6-ft. Frue vanners. A Pelton wheel and 600 ft. of 8-in. wire-wound wood pipe are to be installed this summer. There is a 2-bucket aerial tramway 1500 ft. long. Development includes three tunnels and drifts on the vein at three levels. A winze sunk from No. 3 gives a depth of about 350 ft. from the surface. Up to June 1, as a result of 18 months work, gold to the total value of about \$104,000 had been recovered. Between 500 and 600 tons of first-class ore, shipped crude, averaged about \$116 per ton, while 2750 tons of second-class ore, milled, ran about \$15 per ton.

The Kootenay Belle and Mother Lode are separate groups, situated on opposite sides of Sheep creek. The former is on the south side and adjoins the Yellowstone. On it have been found two parallel veins, 80 ft. apart, one ranging in width from 15 in. to 3 ft., and the other approximately 5 ft. They occur in quartzite and schists cut by aplite or quartz-porphry dikes. In the smaller vein wolframite and scheelite occur, generally near the walls, segregated into bunches or kidneys.

JUNEAU, ALASKA.**Alaska Treadwell.—Douglas Island.—Ketchikan District.**

The large Westinghouse turbines and boilers for the all-year plant of the Alaska Treadwell are expected within a month, and installation will begin immediately on their arrival. It is said that the Treadwell has now the best ore showing in its history. The management has been carrying on experiments for the past year in cyaniding, using a tube-mill and two tanks. The experiments have met with a good measure of success. There are 1200 employees, and 300 more will be put on as soon as the new power-plant arrives. A crew left for Nevada creek, Douglas island, June 17, to begin clearing up the ground and putting up buildings on the property of the Alaska Treasure Co. The mine will be operated this summer under the management of Mike Hudson of Douglas. A discovery of some importance was made on the Jersey group, on Douglas island back of the Treadwell mine. The property is owned by James Mitchell and M. O'Connor of Douglas and William Myers and S. Zinger of Juneau. Last month a rich body of ore was found on the claims of the Chichagoff Mining Co., of Sitka, operating on Chichagoff island. The strike was made in the new adit. A. M. Archangel, the superintendent, has left for San Francisco to purchase additional machinery. It is planned to do away with the present power-plant and install water-power, also to increase the capacity of the mill. At Auk Bay two small mills are to be built this summer. Little development has been done there, but the surface ores give high assay returns.

The Mt. Andrew Iron & Copper Co., operating in the Ketchikan district, made a shipment of 1550 tons of copper ore to the smelter June 19, and will have another ready June 30. The present output, it is stated, will be maintained or increased for an indefinite time. The Mt. Andrew mine now has ore in its new shaft. The Ketchikan district is experiencing a renewed mining activity and a shortage of machine men is reported by mine operators.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Josephinite is found in the placers along Josephine creek, in Josephine county, Oregon. It is an alloy of iron and nickel, containing 60.47% of the latter. When polished it has the appearance of iron or nickel. It is supposed to have been derived from the serpentine rocks of the region and concentrated in the gravels by stream-action.

Superficial high-tenor in copper does not prove that the ore will continue rich in depth. Copper is peculiarly subject to rearrangement by circulation of water through a deposit, and irregular concentrations are likely to result. Prophecy of probabilities requires the ascertainment of the local geological conditions by a trained observer.

Chain-grate stokers are widely used for burning small sizes of coal. In plants carrying uniform loads, where the stokers are properly set, there should never be any smoke. When the load is variable, faulty operation may result in emission of dense smoke. Plants equipped with these stokers can carry a variable load with excellent results if the thickness of fire, speed of the grate, and position of the damper be varied to suit the load.

Rope-drive power transmission may be calculated by a formula proposed by Edwin Kenyon, as follows:

$$\text{Horse-power} = \frac{V (24.6d^{12})}{4860 \times 1000d}$$

in which the horse-power is that transmitted by good 3-strand cotton driving ropes running over pulleys having diameters not less than 30 times the diameter of the rope, and where V equals velocity of the rope in feet per minute, and d equals the diameter of the rope in inches. The arc of contact is assumed at not less than 170 degrees.

Silico-manganese has been introduced as a substitute for ferro-silicon as a deoxidizer to remove occluded gases and oxides from steel, and as a vehicle for carrying either silicon or manganese into the steel. It is used in the open-hearth process, being introduced into the bath shortly before tapping. One advantage claimed for silico-manganese is that it contains practically no carbon, hence does not disturb the temper aimed at in the re-carbonization. Silico-manganese is a product of the electric furnace.

Steel in concrete not only remains clean and bright, but, if the grouting were perfectly done, it is freed from rust by the cement. Recent experiments by Ernest R. Matthews indicate that brickbats are as good as broken stone for the aggregate; that coke-breeze and slag are detrimental; that river sand is undesirable, especially when the concrete is desired to be water-tight; that coating the steel with cement grout previous to pouring the concrete insures protection to the steel; and that the use of oils on the steel reinforcement promotes rather than retards its rusting.

Dry storage of coal has no advantage over storage in the open except with high sulphur coals, where the disintegration of the pyrite facilitates combustion. Submerged coal does not appreciably lose in heat value, but the interest charge on plant and the charge for re-handling adds materially to the cost of the coal. Under-water storage of coal has so far been adopted mainly as a means of securing an adequate supply regardless of strikes.

Enrichment under arid conditions has operated in the Cloncurry district of North Queensland, Australia, to produce large outcrops of rich ore from small veins. In one case 3 ft. of ore at the surface yielding 28 to 40% copper was represented at a depth of 200 ft. by 18 in. with a few stringers of chalcopyrite. In another the ore, a red oxide, gave out at a depth of 10 to 12 ft. The large outcrop in this case was surrounded by small veins 6 to 20 ft. long and 2 to 12 in. wide.

Winter glaciers are accumulations of ice not large enough to persist through the succeeding summer. They are common along the streams of the Yukon-Tanana region, where, contrary to general impression, some water flows all winter in nearly all the streams. Where the channels become clogged this water freezes in masses 12 to 20 ft. thick. These accumulations of ice remain as late as July in sheltered spots, and it has been suggested that by using moss and brush to protect them from the sun, sufficient water might be stored to be of material service in gold washing.

Black sands contain a great variety of minerals, which average from about the specific gravity of tourmaline (3.12) upward. Owing to the similarity of specific gravity among the constituent minerals, the separation of the different materials in the concentrate is difficult. While the great majority of black sands contain nothing of value, there is always the possibility of finding platinum, cassiterite, monazite, and such substances, which would render treatment economical. Well known concentrators are applicable, and separation of iron-bearing minerals may be effected by suitable magnetic separators. It is always well to pan out samples of black-sands and have an investigation of their constituents made by a competent chemist.

Cloud-bursts—concentrated storms of great severity—sometimes take place suddenly in the mountains, in the hottest weather. A cloud may form about a peak, quickly grow dense and black, and be followed by a startling electric display. The lightning is followed by a torrent of rain, the character of the resulting flood depending on the relation of the storm to the topography. If it is concentrated in a canyon, the result is a violent and spectacular flood wave of great erosive and transporting power. If it is spread over an open slope there is a slower moving and less destructive 'sheet-flood'. A large amount of desert erosion, except that due to the winds, is accomplished during brief storms of this kind. Owing to their great irregularity the adequate protection of railways crossing deserts becomes a serious problem.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Co-Operative Topographic Surveys.

The Editor:

Sir—I note in your issue of June 19 the communication of G. O. Smith, Director of the United States Geologic Survey, relative to 'Co-Operative Topographic Surveys'. The difficulty that Mr. Smith has to meet in this matter must be recognized, yet the general dissatisfaction of those in charge of the work of the several States cannot be without some foundation. Unless there is some better arrangement possible than in the past, the present condition will result in dissatisfaction among the members of Congress from the States co-operating. Most of those familiar with the action of Congress relating to the several appropriations for the U. S. Survey for the past few years look upon the 'increase' in the present appropriation as a mere restoration, due to influences from the co-operating States. Many will differ with Mr. Smith in his belief that the claims of the public land States are paramount. The United States Survey is a National organization, and many will think the work should be apportioned, not with reference to Government ownership of lands, but rather with reference to the needs of such work where the greatest industrial developments are taking place, where they will be of immediate use to the greatest number of people. The 'practical' ones will say it should be apportioned in accordance with the taxes paid in the several States for National purposes, which is practically in proportion to the representation in Congress.

It seems clear that the United States fund should be apportioned without regard to whether there is co-operation or not, and if there is co-operation, then the amount of work done will be that much greater, and the United States Survey will get the benefit of it, in common with all others; but there seems no equity in cutting down the allotment in inverse proportion to the percentage of area already surveyed, especially where this increased percentage is due to the use of State funds in co-operative work. Some of the members of Congress have taken the position that the work of the United States Survey should be confined to the areas of public lands, or practically so, and that the several States, where there is no Government land, should do their own surveying, both topographic and geologic. Those who have been familiar with the several appropriations for the United States Survey know of the opposition to these appropriations, and also know that most of the votes necessary to pass them come from more populous co-operating States. The dissatisfaction which has appeared during the last few years with the work of the United States Survey has not been with the topographic work, which has been popular. One of the causes of this has been co-operation. There has been some talk even of a special appropriation for co-operative topographic work.

The whole matter is a complex one and requires careful consideration, but I fear the statement of the position of the United States Survey, and the considerations governing the same, will not prove acceptable to the co-operating States, the proposed allotment will not be regarded as equitable, and the change will lead to an unsatisfied public, reflected in the action of Congress on all the appropriations for the Survey. The position and the 'considerations' governing the Survey in the matter seem a compromise between the needs of those States where the great mass of the people live and the position of the members of Congress above referred to. I well know that Mr. Smith and the officers of the Survey have troubles of their own in working with insufficient appropriations, and with the pressure for work in so many sections of the country. I am not writing for the purpose of criticism, but to call attention to the facts as looked on by those interested in co-operation, with the hope that before the next session of Congress some plan may be evolved that will result in more harmonious action between the Federal Survey and the several State organizations, which will bring them closer together, and thereby maintain and increase the friendly feeling in Congress toward the Federal Survey. Whatever faults we find with the United States Survey are small, and we all need its help. For myself, I expect to do everything possible to help it in any way, even though Pennsylvania has been compelled in the last two years to return to her treasury money appropriated and unexpended by reason of the United States Survey not being able to meet it with an equal amount.

RICHARD R. HICE.

Beaver, Pennsylvania, July 1.

The Editor:

Sir—Concerning the new plan of allotting funds for co-operation in topographic mapping among the several States, announced by G. O. Smith, Director of the U. S. Geological Survey, in the MINING AND SCIENTIFIC PRESS of June 19, I would say that I heartily approve the general principle, since it assures a definite policy, and moreover gives the most work where it is most needed; that is, in those States where the least mapping has already been completed. The only criticism I have to offer is that in making up the percentage of areas already mapped, I do not think it is fair to co-operating States to figure as completed work the old, inaccurate, out-of-date, and abandoned style of mapping on the 1:125,000 scale in vogue 20 to 30 years ago, since all of this work, especially in the Appalachian area, is being re-surveyed on the 1:62,500 scale, and the cost is just as much as though no work had ever been done. The original work was merely a reconnaissance survey, and that of the crudest kind, so that while the old style maps were better than none, they do not reduce the cost of the re-surveys to any appreciable extent. I think this ancient and inaccurate mapping should not be counted in making up estimates of completed work in any State, especially in those where the people are willing to co-operate in paying half the cost of the modern and better map.

I. C. WHITE.

Morgantown, West Virginia, June 29.

Cost Sheet for Mines.

The Editor:

Sir—Frederic Irwin's criticism, July 3, of the cost sheet in the MINING AND SCIENTIFIC PRESS of June 5 is well taken. The language was a bit ambiguous. What I meant was, to include the cost of mining waste in the cost per ton of ore; in other words, to charge all mining, whether above or under the surface. All prospecting, stripping, development or actual ore-breaking would thus be charged to the number of tons of ore mined, which in most cases will be that actually milled or shipped. This is the 'ore'. In the proposed cost sheet this idea was adopted, the figures used were fictions, and a misprint was made in the total value of the ore. Mr. Irwin's objection is based on the wording of a sentence. The context agrees with his deduction. In his own communication, the expression, "the amount of waste should not be considered at all," might be criticised, did not the context suggest a particular and not a general application. For example, if three tons of waste be mined for one ton of ore, one of the objects of a cost sheet could then be realized by making a comparison of the system of screening in vogue with one where some of the then waste could be thrown into the ore. The cost per ton of both mining and milling might be lowered, and the net profit increased, or the change might be unprofitable. All low-grade mines go through this experimental stage. Sometimes, as at Cobalt, the waste rock accumulated in the development stage of the district becomes valuable ore when the milling epoch comes.

Perhaps some of your readers will give a different cost sheet for comparison.

ALGERNON DEL MAR.

South Pasadena, California, July 6.

Progress in Cyanidation.

The Editor:

Sir—An extract from the MINING AND SCIENTIFIC PRESS of January 2 has been brought to my notice, concerning an article by Alfred James on 'Progress in Cyanidation'. Even to a casual reader it would seem that Mr. James' criticisms are biased, in that he appears to favor the extensive use of a certain filtration process, and, in fact, he makes such extensive mention of this particular filtration process as to force upon the reader the conclusion that he may be directly interested in the introduction of that process. Apart from this, however, Mr. James makes an attack on the merits of the Adair-Usher process, which has done such practical work on the Witwatersrand. His criticism is made in a manner which is calculated to mislead the interested reader. Of his many inaccuracies I quote a few: (1) Mr. James states, "The Adair-Usher process thus becomes merely a method, not of solution, but of avoiding with the aid of decantation, a final transfer." This is untrue. The Adair-Usher process only requires sufficient agitation or circulation to dissolve the gold, and the treatment requires no transfer whatever after entering the treatment vat. Furthermore, no vacuum or any other filter is necessary, the charge being finished in this one vat, and is finally expelled therefrom to the dump with a residue that no cy-

nide manager need be ashamed of. (2) Mr. James states, "and sends to the dam an amount of solution containing not less than 4 to 6 grains of dissolved gold per ton, at least equal to the weight of tailing discharged." This our company challenges. The only way this could possibly occur would be by carelessness at the boxes and faulty precipitation, thereby allowing the washing solutions to carry gold. The average gold in solution in the Usher residue is, in practice, from 1½ to 2 grains per ton—a vast difference. (3) Mr. James states, "I saw dirty solution coming off the vats; surely evidence of poor work." This has no bearing on the process whatever. This criticism points merely to inattention and derelictions of the shiftsmen. (4) Mr. James states, "The charge was transferred and allowed to settle before washing started." This is not true. The charge is not settled before washing. The treatment is continuous, and no time is lost before washing is started. (5) Mr. James states, "From careful enquiries I could find no gain in extraction or decreased value of tailing resulting from the use of the Adair-Usher wash." This statement is also untrue, and I challenge Mr. James to disclose the name of the mine using the process, on which his "careful enquiries" were made, and we ask you to compare his answer with the list hereunder of the mines that acknowledge increased extractions alone, without taking into account decreased working costs or increased capacity:

RESIDUES OBTAINED BEFORE AND AFTER ADOPTION OF USHER PROCESS.

| Company. | Before. | | After. | | Saving. per ton. |
|---|---------|--|--------|--|---------------------|
| | dwt. | | dwt. | | |
| Champ D'Or G. M. Co., Ltd..... | 0.5 | | 0.35 | | 0 7½ |
| Crown Reef G. M. Co., Ltd. (treats 8000 tons per month, current and accumulated slime)..... | 0.46 | | 0.37 | | 0 5 |
| Durban Roodepoort G. M. Co. (treat 3850 tons per month on tribute) | 0.7 | | 0.25 | | 1 8 |
| Durban Roodepoort G. M. Co.... | 0.32 | | 0.20 | | 0 6 |
| Ferreira G. M. Co., Ltd. (treats 7175 tons fresh, 1681 tons ac- cumulated slime; total, 8856 tons per month; residues fre- quently as low as 0.12 dwt.; time of treatment, 72 hr.).... | 0.423 | | 0.223 | | 0 10 |
| Geldenhuis Estate & G. M. Co.... | 0.38 | | 0.16 | | 0 10 |
| Jumpers G. M. Co., Ltd. (treats 6000 tons per month current and accumulated slime) | 0.56 | | 0.36 | | 0 10 |
| New West Bonanza G. M. Co. (treats 375 tons per month) .. | 2.50 | | 0.75 | | 7 0 |

Also the Transvaal G. M. Estates treat 4400 tons per month, at a saving of £500. At this mine the time of treatment has been reduced from 5 days 8 hours to 3 days 14 hours.

As a sixth error I may cite Mr. James as follows: "It largely increased the bulk of solution to be handled, 5 or 6 of solution to 1 of dry slime." The ordinary ratio of solutions on the Rand by the old decantation method was approximately 5 or 6 to 1, and the use of the Adair-Usher process does not increase this ratio.

I think the foregoing remarks are sufficient to show that Mr. James' statements are entirely unsupported by facts. Had Mr. James asked our representative for information, this would have been

given him freely, but he appears to have preferred to form his conclusions without satisfying himself as to the accuracy of his information, which is a risky thing for an individual to do when he poses as an authority on such a technical matter as cyanidation.

Mr. James further states that he visited the Ferreira mine, and here again he seems either to have obtained inaccurate information, or to be guilty of a deliberate misstatement. The report of Mr. Hall, the cyanide manager at this mine, given below, supports this, from my point of view:

The slime dropped from collecting to agitating tanks, where it is agitated and circulated from two to five hours with solution 0.02% KCy. The pulp is then transferred to the Usher tanks. These are 6 in number—3 conical bottoms, 50 ft. diam., and 3 flat bottoms, 45 ft. diam., by 12 ft. deep. The average weight of a charge is 150 tons. In the Usher tank, solution is run through at the rate of 12 tons per hour for 36 hours. Another 36 hours is allowed for settlement, decantation, and discharge. The whole time an Usher tank is occupied with one charge is three days. The following table shows comparisons of results obtained during six months (January 1907 to June 1907) immediately preceding the installation of the Usher, and six months (November 1907 to April 1908) following the change. Results obtained during the transition period are not included:

| | Jan. 1907 to June 1907. | Nov. 1907 to April 1908. |
|----------------------------|----------------------------|-----------------------------|
| Average tonnage per month: | | |
| Current | 6,850 | 7,175 |
| Total | 9,032 | 8,856 |
| Value per ton, dwt.: | | |
| Original | 2.866 | 2.637 |
| Residue | 0.423 | 0.233 |
| Extraction, per cent..... | 85.25 | 91.54 |

It will be noticed that the average tonnage per month is less since the introduction of the Usher. This is entirely due to the fact that, through causes having no connection with the change in treatment, the amount of accumulated slime treated has decreased. Residues have frequently been as low as 12 pennyweights.

As to the practical and commercial success of the Adair-Usher process, which Mr. James has been at such pains to discount, may I conclude by recording the fact that H. Eckstein & Co. have recently purchased the entire rights of this process for the many mines under their control, at a substantial figure. This fact alone is surely a sufficiently convincing proof as to the value of the Adair-Usher process.

GEO. MACKENZIE.

Johannesburg, Transvaal, May 26.

Three regions in Alaska give promise of making important contributions to the copper market—Prince of Wales island, Prince William sound, and the Copper River-Chitina River region. The first two, which are near the sea, have produced copper for several years, but the third, which lies inland, is still in the prospecting stage. A report on this region by F. H. Moffit and A. G. Maddren has just been issued by the U. S. Geological Survey as Bulletin 374. Copper was the first mineral found in Alaska, and seems likely to be mined there in quantity.

VIRGINIA GEOLOGICAL SURVEY FOR THE SEASON 1909.

At the June meeting of the State Geological Commission held at Richmond, the following plans and appointments for the season's work were approved: (1) Continuation of the Virginia Coastal Plain surveys in co-operation with the United States Geological Survey, under the direction of W. B. Clark and T. W. Vaughan. Detailed work in the Coastal Plain province has been in progress for several seasons, and it is expected that by the close of the present season the field work for the entire area will be completed. (2) Continuation of the topographic and geologic surveys of the Virginia portion of the Virginia copper district. The four topographic sheets covering this area are being mapped in co-operation with the U. S. Geological Survey. The present season will allow the completion of detailed geologic mapping of the district by F. B. Laney of the State Survey, assisted by J. H. Watkins. The work will represent the most careful and accurate geologic study yet made of any part of the southern crystalline area. (3) Continuation of the detailed mapping and study of the Nelson county rutile area by T. L. Watson, State Geologist, and Stephen Taber. The work in this important, and as yet the only known commercial area of rutile in the United States, will be completed during the present season. (4) Continuation of the building stones work, under the direction of Mr. Watson. Special attention is being given the slate areas, of which there are four. J. S. Grasty is in charge of the work in the Arvonja and Snowden areas, Justus H. Cline is studying the Fauquier-Culpeper counties area, and S. L. Powell is investigating the Quantico belt, in Spottsylvania, Stafford, and Prince William counties. (5) Investigation of the iron ores of the State is being continued by R. J. Holden. H. D. Campbell is mapping the areal geology comprised within the Lexington, Natural Bridge, and Lewisburg topographic sheets. The chemical division of the Survey is in charge of Wm. M. Thornton, Jr.

Fluorspar mines in Illinois produced in 1908 34,918 short tons with a value of \$192,179, according to statistics collected by the State Geological Survey and the U. S. Geological Survey in co-operation and published in circular No. 5 of the former bureau. This was an increase of 9790 tons or 38.9% over the quantity produced in 1907, and an increase in value of \$50,208. There remained some \$7918 worth of unsold stock at the end of the year, and these figures are included in the production given. While the general business depression prevented the running of the mills at their maximum capacity, some impetus was given to the industry by the increased use of fluorspar in the manufacture of open-hearth steel. Doubtless the development of the new plant at Gary, Indiana, will greatly increase the demand for fluorspar from the Illinois mines.

Sumatra mining is developing. A company has been organized to work valuable deposits of silver, gold, and copper in the Lampeng district.

PHOSPHATE DEPOSITS OF UNITED STATES.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK B. VAN HORN.

*As a result of the recent 'conservation' movement, a good deal of attention has been directed toward phosphate rock and its importance in the welfare of the nation. When it is considered that many varieties of plant life cannot exist without the presence of phosphoric acid in the soil, the conservation of our deposits of phosphate rock becomes a question of great importance. Growing crops deplete the soil of its phosphoric acid, and if no steps be taken to restore it, the soil must eventually become non-producing.

The known phosphate deposits of the United States are distributed among four localities: (1) along the west coast of Florida; (2) along the coast of South Carolina; (3) in central Tennessee; and (4) in an area comprising southeastern Idaho, southwestern Wyoming, and northeastern Utah. In addition to these areas, some deposits occur in north-central Arkansas, along the Georgia-Florida State line, in North Carolina, Alabama, and in Mississippi, but these are mainly low-grade, and are not utilized at present. Besides these low-grade phosphates, according to Oscar H. Hershey, apatite rock ranging from 9.62 to 15.7% phosphoric acid has been found in connection with iron ore deposits in Eureka county, Nevada. Mr. Hershey estimates the supply at about 500,000 tons. Of the four producing fields, three have been worked from 14 to 30 years, while the Idaho-Wyoming-Utah field is a comparatively recent discovery which has had but a small output.

Phosphate mining began in the United States in 1867 in South Carolina. The existence of the rock has been known since 1837, but the possibilities of its commercial use were not recognized until 1859. From 1867 to 1888 South Carolina enjoyed a monopoly of the phosphate industry of the United States. In the latter year Florida came forward as a phosphate State, with a production of 3000 long tons. In 1904 the production surpassed that of South Carolina, and Florida has maintained its lead up to the present time. In 1892 phosphate was discovered in Tennessee, and two years later the production from that State was 19,188 long tons. In 1899 Tennessee went ahead of South Carolina, the production from the latter State having decreased steadily since 1894. The phosphate deposits range in age from the Ordovician in Tennessee to the Tertiary in Florida, occurring also in the Devonian in Tennessee and Arkansas, and in the Carboniferous in the Idaho-Wyoming-Utah field.

In Florida are three classes of deposits—'hard rock', 'land pebble', and 'river pebble'. These deposits vary in percentage of tricalcium phosphate from 78 to 80% in the hard rock, from 68 to 70% in the land pebble, to about 65 in the river pebble.

The hard rock phosphate belongs to the Eocene and the Miocene periods. In the former it consists entirely of a boulder deposit in a soft matrix of phos-

phatic sands, clays, and other materials, while in the latter it is also found at many places as a bedded deposit in place. The boulders vary in size from 2 or 3 in. to 8 or 10 ft., and lie embedded in all positions, surrounded by sand and clay containing considerable phosphate of lime in fine particles, resulting from a general distribution of the disintegrated portions of the boulders during deposition. The deposits themselves vary from small pockets to those several acres in extent. The phosphate content of this class of deposit is from 10 to 30% of the mass.

The pebbles making up the land pebble deposits range from minute size to that of a walnut. They are originally white in color, but become dark colored

Phosphate Deposits in the Southeastern States

when subjected to the action of water. They are embedded in sand and are underlaid by a stratum of tough, stiff, clayey material known as 'bedrock'. Above the deposit is an overburden from 1 to 25 ft. thick, consisting of sand and limestone boulders. The proportion of phosphate to other rock of this class of deposit varies from 10 to 25 per cent.

River pebble phosphate is similar to the land pebble, and derives its name from its manner of occurrence in the river beds. The pebbles are white to dark brown in color, and of about the same size as the land pebbles. They occur in the form of bars in the rivers, and are derived from the formations through which the river flows.

In South Carolina the phosphate rock occurs in two forms: the land rock and the river rock, analyzing

*Published by permission of the Director, U. S. Geological Survey.

about 58 and 55%, respectively, in tricalcium phosphate. The land rock is probably of Miocene age, and consists of so-called 'pebble rock', which is in fact a solid mass from which the calcium carbonate has been leached and partly replaced by phosphate, leaving cavities which connect and penetrate the rock, giving it the appearance of being made up of separate pebbles. The rock is from 1 to 3 ft. thick and is overlaid by a green-sand marl. The river rock is so called because it is mined from the river channels. It consists essentially of the water-rounded fragments of the land rock.

In Tennessee there are three commercially important classes of phosphate rock—the brown residual phosphate, the blue or black bedded phosphate, and the white phosphate. These range in phosphatic content from 70 to 80% lime phosphate in the brown

20 in. thick. The phosphatic content ranges from 30 to 85%. The nodular variety, which is embedded in a green-sand matrix, runs about 60% lime phosphate, but it is not practicable to work it except at points where the bedded rock is mined by stripping the overburden.

White phosphate rock is of post-Tertiary age, and occurs in three different forms—stony, brecciated, and lamellar. The stony phase contains usually only about 50% of lime phosphate, and is not worked at the present time. The lamellar forms were deposited in caves, and are thus of irregular shape and extent. The breccia consists of fragments of Carboniferous chert cemented by lime phosphate. The chert fragments vary from a fraction of an inch to 3 or 4 in. diam. The lamellar variety consists of thin parallel layers or plates about 1 in. thick, but several inches long and broad. The white phosphate has thus far been found only in Perry and Decatur counties. It contains sometimes as much as 85% phosphate of lime.

Within the last few years a large area of phosphate-bearing rock has been discovered in the western United States. This discovery is of much importance, since it opens a new field in an area tributary to great agricultural regions. The phosphate occurs over a considerable area in southeastern Idaho, southwestern Wyoming, and northeastern Utah. It is found in rocks of Upper Carboniferous age in a series of shales and limestones, 100 ft. thick, within which are several beds of phosphate rock ranging in thickness from a few inches to 10 ft. At the base of the series is a limestone, and 6 to 8 in. of soft brown shale separates this from the principal phosphate bed, which is 5 to 6 ft. thick. This phosphate bed is oolitic in character, and is high in phosphoric acid. There are in the series several other beds ranging from a few inches to 10 ft. thick, separated by thin beds of limestone or shale. Usually one and sometimes two of these beds at a given section are workable, and probably some of the others will eventually be mined. The lime phosphate content in the workable beds varies from 65 to 80%, with an average of 72. The newness of the field, the lack of transportation facilities, and the high freight rates have prevented the development of this phosphate territory to any great extent, although there has been some shipment from Montpelier, Idaho, in the last three or four years. According to F. B. Weeks,[†] who recently prepared a preliminary report upon these phosphates. This field embraces the largest area of known phosphate beds in the world, and at some future time it will doubtless furnish a large part of the world's production of commercial fertilizer. The development of intensive farming as a result of the reclamation of arid lands in the West will afford an increasing home market.

On December 10, 1908, acting under instructions from President Theodore Roosevelt, the Secretary of the Interior withdrew from entry all the public lands in the above three States believed to contain phosphate rock—about 7500 square miles. The list

[†]Contributions to Economic Geology, 1907, Pt. I; Bull. U. S. Geol. Survey No. 340, 1908, pp. 441-449.

Phosphate Lands in the West.

rock to 75 to 85 in the white rock, although in all three classes are to be found portions which run as high as 90%. The brown residual phosphate occurs mainly in Maury county. It is of Ordovician age, and is the result of the leaching process to which the phosphatic limestones have been subjected. Surface waters bearing carbonic and other organic acids have dissolved and carried away a large part of the calcium carbonate forming the limestone, leaving the tricalcium phosphate as a residual deposit. The brown phosphate is from 2 to 6 or 8 ft. thick at various points.

Blue or black bedded phosphate deposits are of Devonian age, and show variations from oolitic through compact and conglomeratic to shaly forms. There is also a nodular variety which occurs in a green-sand formation immediately overlying the black shale. The bedded deposit occurs in seams varying from 1 to 50 in. thick, but where carrying high-grade rock the bed is seldom more than

of lands withdrawn was furnished by the United States Geological Survey, as a result of preliminary examination. On June 1, 1909, the Survey placed a party in the field for the purpose of classifying these lands in detail and getting accurate knowledge of the deposits. It is not to be supposed that the entire area withdrawn will be found to contain workable phosphate, and at the end of the present field season some of the withdrawn territory will undoubtedly be restored to entry. Furthermore, knowledge concerning the extent of the phosphate deposits of the West will be in a much more advanced state than at present.

The total production of phosphate rock in the United States from the beginning of the industry to the end of 1908, by States, has been as follows:

| | Tons. |
|----------------------|------------|
| South Carolina | 12,138,454 |
| Florida | 14,087,833 |
| Tennessee | 5,315,422 |
| Other States | 52,570 |
| Total | 31,594,279 |

Owing to incomplete data, any estimate as to the available supply of phosphate rock must at best be unsatisfactory. Sufficient work has not been done with the view of figuring supply to give a reliable estimate. It is known that the phosphate rock of South Carolina is practically exhausted; the Florida deposits have probably reached their maximum production; the output of the Tennessee deposits is on the increase, but this field alone would at the present rate of increase in production last but a comparatively short time. After the exhaustion of the Southern deposits there remain only those deposits of low grade already mentioned, and the large deposits of the public land States, upon which we must depend for the greater part of our phosphate in the future. Such estimates as have been made indicate the following reserve of high-grade phosphate rock in the United States:

| | Tons. |
|----------------------|-------------|
| South Carolina | 3,000,000 |
| Florida | 15,000,000 |
| Tennessee | 103,500,000 |
| Western States | 100,000,000 |
| Total | 221,500,000 |

It may be necessary to increase these estimates, and it is to be remembered that these figures are only for high-grade rock, that is, rock containing from 60 to 85% tricalcium phosphate. In addition, the vast amount of low-grade rock which is not now available will be in reserve, and some time before the exhaustion of the high-grade deposits we shall doubtless have begun to use this rock. The increasing price of the 60 to 80% phosphate will have a hastening effect on the utilization of the present low-grade material. The deposits of Arkansas, Georgia, North Carolina, Alabama, Tennessee, and the West, which run from 30 to 50% in lime phosphate, will be available to draw upon after the high-grade rock is exhausted. This class of deposits, especially in Tennessee and the Western States, will afford an enormous tonnage. The accompanying sketch maps show the areas in the United States in which phosphate rock is known to occur.

MANGANESE IN THE UNITED STATES.

A detailed report on the manganese deposits of the United States, by E. C. Harder, of the U. S. Geological Survey, is now in press. The preliminary paper, just out, contains notes on the sources and uses of manganese and the present status of the industry, together with brief descriptions of the principal localities where the ores are obtained. The manganese mining industry in the United States has for several years past been very small. In 1907, despite the general industrial activity, less than twenty manganese mines were in operation and not half that number operated steadily. The large manganese districts of the United States are in the Valley and Piedmont regions of Virginia, at Cartersville, and Cave Springs in Georgia, and near Batesville, Arkansas.

Manganese ores comprise the oxides and the carbonate of manganese. The most abundant deposits are in the Appalachian and Piedmont regions, in the southern part of the Mississippi Valley, and on the Pacific Coast. Manganiferous iron ores consist of a mixture of any oxide or the carbonate of iron with any oxide or the carbonate of manganese. They occur chiefly in the New England, Appalachian, and Lake Superior regions. Manganiferous silver ores consist of a mixture of manganese and iron oxides with small amounts of silver sulphide and lead carbonate, and in some places of gold. They are found in the Rocky Mountain and Great Basin regions. Manganiferous zinc residuum is obtained from the zinc furnaces in the Franklin Furnace district, New Jersey.

The chief producing States at present are Virginia, Tennessee, South Carolina, and California. In Virginia the principal deposits are in the James River valley near Lynchburg, on the west slope of the Blue Ridge from Front Royal to Roanoke, and in several belts in the New River region. The Tennessee deposits are the southward continuation of those of the Appalachian valley in Virginia, and occur mainly in Cocke, Unicoi, and Johnson counties. In South Carolina the most important deposits are near McCormick, in Abbeville county. The principal California deposits are near Livermore, in Alameda and Santa Clara counties.

The uses of manganese in the industries are metallurgical, in the manufacture of alloys and in copper and silver reduction, and chemical, as an oxidizer and a coloring agent. The principal alloys, spiegel-eisen and ferro-manganese, are used in various ways in the steel industry, the addition of small quantities of manganese giving to steel hardness, ductility, and strength. Manganese bronze is used for steamboat propellers, and other alloys are used for coins, statuary, and ornamental purposes.

Little manganese ore is now mined in the United States, the total in 1907 being only 5604 tons, against 209,032 tons imported, chiefly from India, Brazil, Cuba, and the East Indies. The average grade of the domestic ores is much lower than that of the imported ores and they require considerable treatment to prepare them for the market.

HISTORICAL GEOLOGY OF CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

(Continued From Page 582, June 10.)

Tertiary (Cenozoic).

Southern California. The lowest Eocene formation in southern California is the Topatopa, which consists of quartzite, sandstone, and shales, the former predominating in the lower and the latter in the upper portion. This formation occupies the heart of a large anticline, of which the eastern limit is the east wall of Sespe canyon, while westward it extends to Santa Barbara. It also forms the heart of Cayetano mountain. Characteristic Eocene fossils have been obtained from its upper portion.⁹⁶ The lower portion may be equivalent to the Martinez. The Sespe formation consists of sandstone and conglomerates, with thin bands of shale and occasional bodies of white limestone. The sandstone is generally of a reddish-brown color, except the white oil-bearing strata at the base, and a ferruginous, greenish-gray, calcareous sandstone in the upper horizon, which is the probable source of the oil in Tar creek. The major portion of the Sespe formation is certainly Eocene, but its gradual transition into the overlying Vaqueros renders it doubtful whether the upper portion may not belong to the Oligocene.⁹⁷

In the Santa Clara region (Ventura and Los Angeles counties) the Vaqueros consists principally of shale, generally with a basal formation of sandstone and conglomerate.⁹⁸ The Modelo formation overlies the Vaqueros conformably. It bears, both from a lithological and a paleontological standpoint, a marked resemblance to the Monterey. At its base is a massive, heavy-bedded, white to yellowish-gray sandstone, containing large concretions, and usually stained with petroleum. This sandstone forms a conspicuous horizon, distinguishing the underlying Vaqueros shales from the overlying similar Modelo shales. Within the latter is a member of light-colored sandstone.⁹⁹

In the Puente hills, southeast of Los Angeles, the Miocene is represented by the lower Puente shales, which may be Oligocene; the Puente concretionary sandstone; and the upper Puente shales. The Puente sandstone and the upper shales are also found in Los Angeles and along the flanks of the Santa Monica range. Along the Santa Monica range and in the Puente hills large masses of Miocene basalt are associated with the Puente formation. In the Puente hills the oil is principally derived from sandy strata in the lower Puente shale. At Los Angeles the productive oil-sands occur near the top of the Puente formation.¹⁰⁰

After the close of the Middle Miocene a general disturbance must have occurred in the northwest-

ern portion of southern California, causing a general unconformity between the Middle Miocene and the overlying Fernando formation. This formation extends from the Upper Miocene to the Pleistocene (see above, Coast range). It is possible to subdivide the formation locally, but over a considerable extent of territory these divisions merge into one another by insensible gradations. An unconformity generally marks the top as well as the base of the formation. It consists of a succession of conglomerates, sandstones, and arenaceous clays. At the Puente hills the formation carries considerable granitic detritus. In that district the Fernando has proved extremely rich in oil in several localities. In the vicinity of Los Angeles the basal portion of the Fernando consists of thin-bedded sandstone, overlaid by hard shale, rich in gypsum, in turn overlaid by sandstone, conglomerate, and shales, yielding Pliocene fossils. There is decided evidence of a break between the Puente Miocene white shale and the Pliocene strata, but it has not been determined what plane in the sequence of beds marks this period, because the usually discernible unconformity between the Monterey shale and the subsequent formations appears to be lacking. The arbitrary line between the Miocene (Puente) and the Pliocene (Fernando) has been drawn at the top of the uppermost layer of hard, white shale.¹⁰¹

In the upper drainage of the Santa Clara river the Tertiary rests directly upon the granitic rocks. These Tertiary formations are intercalated with lavas and tuffs, probably flows from a centre of eruption near the head of Soledad canyon. The lower formation (the Escondido series) is differentiated from the upper (the Mellenia) by the fact that the conglomerate of the former consists of granitic pebbles, while those of the upper are chiefly of lava derived from the lower series.

In the Antelope valley is a range of hills east of Rosamond, formed of rhyolite tuffs, intercalated with sandstone, remarkable for their brilliant colors. These are probably Tertiary strata, and form the Rosamond series.¹⁰²

Both slopes of the range on the peninsula are bordered by Tertiary strata. At Carizo springs, on the east slope, decided Miocene fossils have been collected. Eocene fossils have been found at a few points on the coast near San Diego. North of Santa Margarita creek the Tertiary forms the San Onofre mountains.

The northern portion of the Santa Ana range consists of Tertiary strata. The numerous eruptions of lava in southwestern California are of Tertiary age. At that time an uplift, accompanied by faulting, took place, and through the resulting fissures the lava-flows were erupted.¹⁰³ The conformation of the San Diego mesa, the San Pedro, and the San Clemente islands, prove that the sequence of the post-Miocene uplift, the long period of erosion, and the Pliocene period of depression, above set

forth as the geological sequence in the Coast range, also holds good on the coast of southern California.¹⁰⁴

Quaternary.

Sierra Region. The Pleistocene was, in its beginning a period of rest and erosion, during which the rivers cut their present canyons; then occurred extensive basalt-flows, which are found along the slopes of the higher Sierras, and to which belong the doleritic basalt of Mt. Ingalls, Plumas county. This basaltic eruption was the last volcanic activity within the Sierra Nevada, west of the summit.¹⁰⁵ This was succeeded by the Glacial epoch, during which the Sierra Nevada was covered by an immense snow-field, which probably stretched continuously from a little north of latitude 36° nearly to 40. The width of the snow-belt was irregular, but averaged from 10 to 15 miles. This glaciation was of an Alpine character; it had no connection with a northern ice-sheet. The remains of this Glacial epoch can be seen in the cirques and moraines of the higher Sierras.¹⁰⁶ Lower down the western slopes of the Sierra Nevada are found the Pleistocene river shore-gravels and Pleistocene lake-beds. The lower portions of the slopes were still beneath the level of the gulf waters, and thereon were deposited beds of gravel, hardpan, and clay, which cover an extensive area on the east side of the San Joaquin and Sacramento valleys; these in turn are overlaid by late Quaternary alluvium.¹⁰⁷

Northern California. In the Lassen Peak region volcanic activity has persisted during the Quaternary up to recent times. Mount Shasta has also been an active volcano during the late Quaternary. Its basalt-flows cover a large portion of Shasta valley and the country to the east, and the flow has run down the Sacramento canyon. The centre of the northern end of the Sacramento valley is covered by the Pleistocene Red Bluff formation, a fluvial deposit of gravels and sand lying unconformably upon the Tuscan tuffs and older formations, and in turn overlaid by late Quaternary alluvium.¹⁰⁸ During the Glacial epoch part of the Klamath mountains was covered by ice. Glacial remnants are found in the Yallo Bally, Salmon, and Trinity mountains; the amount of erosion since the ice disappeared is so small that the glaciation must have occurred in a late portion of the Glacial epoch.¹⁰⁹ As the Pleistocene was a period of uplift and erosion, no Pleistocene sediments are found in the Klamath region.

Coast Range, Including the Coast of Southern California and the Interior. A post-Pliocene epeirogenic uplift of the entire coast from Del Norte to San Diego has been fully established. In northern California this uplift amounted to 1600 to 2100 ft., and in south-

ern California from 800 to 1500 ft. This uplift occurred in stages, well marked by the terrace formations, which can be readily observed in the river valleys and on the coast. The satisfactory line of demarkation between the Pliocene and Pleistocene, on a purely paleontological basis, will probably never be formulated, and it appears more advisable for the Pacific Coast to draw the line of demarkation at the reversal from the epeirogenic Pliocene depression to the epeirogenic post-Pliocene uplift. During this Pleistocene period of uplift two remarkable local depressions took place, one at Catalina island, the other forming the bay of San Francisco.¹¹⁰ As the result of this stage-like uplift the Pleistocene marine deposits (Terrace formation) were spread over the terraces, representing deposits which accumulated off-shore at various stages of the emergence. They are composed of light-yellow sands, generally well stratified but not consolidated.¹¹¹ Apparently some volcanic activity must have occurred locally on the coast, for at Carmelo bay sheets of lava are intercalated in the earlier Terrace formation.¹¹² Within the northern Coast range are extensive basalt flows contemporaneous with those of Mt. Shasta above mentioned.¹¹³ On the coast of San Luis Obispo county is evidence that after the Pleistocene uplift a slow subsidence has set in, during recent times.¹¹⁴ In Santa Barbara county the Pleistocene consists of detrital deposits which cover the slopes at the base of the mountains, and marine deposits which skirt the coast; also of clays and fine sands forming terrace deposits mostly of marine origin, dune sands, and alluvium. The terraces fringe the coast-line and the valleys, and cover areas of low hills. Dune sands have been accumulating all through the Quaternary, continuing up to the present. The recent alluvium cannot be distinguished from the Quaternary alluvium. Near Summerland the Lower Pleistocene is oil-bearing in places.¹¹⁵ Neither in the Santa Clara valley nor at the Puente hills is the Pleistocene oil-bearing,¹¹⁶ but in the vicinity of Los Angeles the Pleistocene is in some localities impregnated with asphaltum.¹¹⁷ San Pedro, near Los Angeles, is the type locality for the fossiliferous marine Pleistocene on the coast, which therefrom has been given the name of San Pedro formation.¹¹⁸

During the last year the Antofagasta & Bolivia Railway Co. transported over its lines the following quantities of mineral products: nitrate, 382,800 tons, the output of 16 works or 'oficinas'; metals from the Huanchaca mines, 47,500 tons; tin and copper ores, 125,500 tons. These figures represent substantial increases over last year.

DOES AN AUSTRALIAN KIMBERLEY EXIST?

Written for the MINING AND SCIENTIFIC PRESS
By JOHN PLUMMER.

Since the first discovery of diamonds in New South Wales, over half a century ago, many thousands of small stones have been obtained in various parts of the State. The diamantiferous localities are numerous, but not the slightest trace of the source of the stones has hitherto been discovered. Small diamonds have also been found in Victoria and South Australia. In New South Wales the stones occur in Tertiary outliers representing old river accumulations. These are of more than one geological epoch. They lie at various distances from present river channels, and once formed portions of widespread and continuous deposits, resting on the bedrock of the country. The diamonds also occur in the recent gravels derived from the Tertiary deposits. About twenty years after their first discovery in New South Wales, extensive discoveries were made at Bingara, in that State, but the smallness and hardness of the stones made them commercially valueless. The larger dia-

Elevator at Diamond Washing Plant.

(with occasional rounded pebbles) of other rocks, such as clay-stone, amygdaloidal basalt, quartz-felsite, eclogite, etc., with garnets, chrome-diopside, magnetite, zircons, and a considerable quantity of secondary calcite." Systematic investigation led to the conclusion that Ruby hill is the denuded remnant of a volcanic pipe, formed, during Tertiary times, at the junction of an old intrusive quartz-felsite with the Carboniferous sediments. Subsequently the eclogite, which Australian geologists now almost unanimously regard as the actual matrix of the diamond, was much altered. Recently specimens of eclogite have also been obtained near Delegate, a New South Wales township close to the Victorian border. The rock is found at Kimberley in rounded masses having a singularly close resemblance to water-worn pebbles and boulders, and is coarsely crystalline and granular, the color being dark green, or almost black, showing some bright red garnets and other rare minerals. The resemblance between the Kimberley and Australian eclogite is sufficiently close to suggest a common origin.

E. J. Dunn, the Director of Geological Survey of Victoria, in a paper read before the Royal Geological

Australian Diamond Washing Plant.

monds are now readily cut with the assistance of diamond dust. Twenty years ago an official report stated that the New South Wales diamonds, in their physical characteristics, were more nearly allied to those of Brazil than to those of any other country, and that in color they differed but little from those of other fields. The general absence of 'cleavage' and 'maches' is a point in their favor.

Considerable diversity of opinion has existed with respect to the origin and true matrix of the Australian diamonds, but within the last few years it has become generally accepted that they will ultimately be traced to volcanic pipes analogous to those found on the Kimberley field. Recent discoveries, especially that at Rube hill, in the northern portion of the State, tend to confirm that conclusion. This hill on three sides exposes a volcanic breccia, which bears a striking resemblance to the volcanic agglomerate of the Kimberley pipes, the principal difference being that the local rock shows no sign of serpentinization. It has been decomposed to a depth of only a few feet, and in its undecomposed state it is of a dark greenish-blue color. "It is," we are told, "made up chiefly of angular fragments and masses

Society in London some few years ago, attributed the origin of the Kimberley diamonds to the beds of carbonaceous shale forming the walls of the volcanic pipes near the surface. He directed attention to the occurrence in all of the mines of considerable deposits of black carbonaceous shale underlying the beds of gray shale. These carbonaceous shales, according to Mr. Dunn, were over 100 ft. in thickness, and extended horizontally over the whole of the country in which the pipes existed. That the Kimberley mines are volcanic pipes, and that they burst through the carbonaceous shales, he regarded as evident, and in addition stated that it was found that the yield of diamonds in these pipes was greatest when mining was carried on in those portions of the pipes surrounded by carbonaceous shales, rendering it probable that these latter supplied the element necessary to produce the diamond, which is simply pure carbon. The pipes, it may be explained, extend to unknown depths, suggesting a chimney or vent from some deep-seated focus of thermal activity. It was supposed that the intense heat of the escaping lava bursting through the shales assisted in forming the diamond. The presence of eclogite in the Kim-

berley mines, combined with its discovery in New South Wales, where the carbonaceous shales are of such vast extent and thickness, especially in connection with the discovery of myriads of diamonds, the source of which has yet to be found, naturally suggests the possibility of an Australian Kimberley. On the other hand, it has been ascertained that diamonds are found below the limits of the carbonaceous shales. In the Kimberley mines exploratory work has been carried down to a depth of 1800 ft., while the carbonaceous shales, of Mesozoic age, do not extend more than 320 ft. below the surface. Notwithstanding this fact, diamonds are found as plentifully in the bottom of the mine as they were in the upper levels and above the carbonaceous shale. This has caused many to consider that the carbonaceous shale has nothing to do with the formation of diamonds. That diamonds are the result of volcanic action is unreservedly admitted. T. G. Bonney has expressed the opinion that the stones are probably derived from the destruction of rather coarse peridotites, pyroxenites, and eclogites. It is the presence of the latter, which is now beginning to be regarded as the real matrix of the diamond, in all the Kimberley mines, which causes its discovery in Australia to be regarded with such interest. In his work on the 'Minerals of New South Wales', E. F. Pittman, State Geologist, says: "It has yet to be proved whether the Ruby hill agglomerate contains diamonds in payable quantities; it may be that it does not, but the occurrence of one such deposit renders it extremely probable that others may exist, and that the presence of diamonds in the basalt-covered gravels of Boggy Camp, Bengara, and Cudgegong, is due to the denudation of these volcanic pipes, and the re-distribution of their contents in the drainage channels of the Pliocene age." The recent discovery of eclogite in the State would appear to confirm the view expressed by Mr. Pittman, who thinks, however, that the creeks in the vicinity of the alleged pipe should be examined, with a view to ascertaining whether there are any traces of diamond-bearing breccia.

GUNNISON COUNTY, COLORADO, MINERALS.

Some of the mining camps of southeastern Gunnison county, Colorado, recently described by J. M. Hill, of the U. S. Geological Survey, were discovered as early as 1878. The first rush of miners began in 1879 and 1880, and by 1881 the work in most of the camps was in full swing. By 1883 the production of the mining districts was estimated by the Director of the Mint as follows: Tincup, \$405,000; Tomichi, \$400,000; Quartz Creek, including Gold Brick, \$195,000. From 1903 to 1907 the statistics given by the U. S. Geological Survey in the annual volumes of 'Mineral Resources' show the production of the districts as follows: Box Canyon: gold, \$1351; silver, \$35; most of the output being in 1906 and 1907. Districts south of Tomichi creek: gold, \$41,384; silver, \$4257. The mines of this district were most active in 1903 and 1906. Gold Brick: gold, \$79,074; lead, \$6082. The years 1906 and 1907 show the greatest production, though this district has been a constant producer since 1903. Quartz Creek: silver, \$97,115; gold, \$4600; zinc, \$3452. From 1903 to 1905 the mines of this district were fairly active. In 1906 the production fell off, and in 1907 none of the mines were producers. Tincup: silver, \$30,198; gold, \$15,757; lead, \$6132. Up to 1906 silver was the chief metal saved. In that year, however, probably owing to improvements in treatment, the gold values show a big increase. Tomichi: lead, \$19,314; silver, \$13,219; copper and zinc, \$10.642; gold, \$1638. This has always been a silver and lead district, though in 1903 and 1905 some gold was recovered.

DRILL-LOG FOR PLACER GROUND.

The following table is taken from the log-book kept by William H. Radford in drilling a placer, and represents an excellent form for the purpose. The simplicity of the form is a meritorious feature. A log-book should be free from complications. The attempt to keep elaborate notes in the midst of the daily routine of testing is liable to lead to confusion and error.

Form for Keeping Drill Log in Prospecting Placer Ground.

BEDROCK AT 15 FEET.

Depth = 15 ft. — 15 × 0.27 = 4.05 cu. ft.
A's recovered = 0.55 grains — 0.55 × 3.25c. = 1.79c.
132 in. driven in the pay-streak gave 185 in. of core.
132 in. = 0.71 — 1.79 × 0.71 = 1.27c.
185 in.
4.05 : 27 :: 1.27 : x.
x = 8.46c. per cu. yd.

R. C. 6 = 8.46c. PER CU. YD.

A = Number of inches drilled before driving.
B = Number of inches driven.
C = Number of inches of core in casing.
L = Large colors.
M = Medium colors.
F = Fine colors.
S = Specks.

ENGINEERING RESPONSIBILITY.

By CHARLES B. DUDLEY.

*Closely connected with the query as to the cause of failures is the oftentimes more important question, who is responsible for the failure? If the matter in hand is an experiment which we are making for our own information, the question of responsibility is small and is practically swallowed up in the cognate question of the cause of the failure. But if, on the other hand, the failure involves the loss of human life or the destruction of valuable property, the question of responsibility may be grave. The placing of the responsibility for failure is not always an easy matter. In our studies of failed and broken parts in connection with our work at Altoona for some years, we have been gradually led to ascribe failures to one or more of the four following causes: bad material, bad workmanship, bad or faulty design, or unfair treatment.

Bad material does not cover those cases where the wrong kind of material was used or material not adapted to the work. If cast-iron is used when steel should have been employed, if the steel is brittle when the service requires tough tenacious metal, this is no fault of the material. Failures due to the employment of material unfitted to the service come under another category. Nor can the material be blamed if the size of the part which fails is too small. This cause of failure also comes under another category. But material is bad, and may justly be charged with being the cause of failure when it is different from what those who put it in service had a reasonable right to expect it to be.

The query may naturally arise here, ought not the factor of safety employed to be sufficient to care for the uncertainties of material, so that the total output of a works could be made use of in service? Undoubtedly there is a necessary relation between the factor of safety and some of the uncertainties of manufacture, but it can hardly be allowed that the producer should throw upon the consumer all the uncertainties of material. I cannot help thinking the following definition of bad material is sound: Material is bad when it is different from what those who put it in service had a reasonable right to expect it to be. If the material is bought on specifications, it is reasonable that it should be what the specifications call for. And even if it is bought on indefinite, verbal, or written order, such material should be supplied as the buyer had a reasonable right to expect would be furnished.

But why is there ever any difficulty between the producer and consumer about material? The price is agreed upon when the order is taken and the quality of the material is either specified or understood. Why, then, does not the producer always furnish good material?

Our experience on this point has brought us face to face with several explanations of the difficulty we are considering. First, and perhaps most important, is the price. It is constantly urged that the consumer will not pay the price requisite to secure

the materials desired. No information is usually given as to how far the wished-for price, requisite to secure such good materials as the producer would like to furnish, covers a desire for large profits, and consequently consumers have always been a little slow to attach much weight to this excuse. Prices are largely determined by competition, and in the absence of something more than a verbal statement from the producer that better materials would be furnished at a higher price, he would be a bold purchasing agent who would pay the higher rate. On the other hand, it is undoubted that competition is the antagonist of quality, and where materials are bought without reasonable specifications rigidly enforced, there is unquestionably much weight in the contention of the producer.

Another reason or excuse for poor materials is that the processes and methods of manufacture do not always and every time yield the desired first quality product. Strive as the manufacturer may, the works always turn out some material that is inferior.

Another and most pernicious excuse for furnishing bad materials is the attempt on the part of producers to usurp the legitimate functions of both the consumer and his expert. This manifests itself in the statement, so commonly made by those furnishing material, that it is good enough for the purpose, thus arrogating to themselves the right to decide not only how the material shall be made, but also what kind of material the consumer and his engineer shall use. Pernicious though this custom may be, a good deal may be said in palliation of it. The practice is the outgrowth of a historical situation. In the earlier days, when the consumption of materials was only a fraction of what it is at present, the producer of any material was supposed to know not only how to manufacture it, but also its characteristics and how it would behave in service, and consequently consumers who in those days had scarcely begun to study for themselves the behavior of materials in service, naturally turned to the manufacturers for counsel as to what materials to use.

The second cause for failure in structures, bad workmanship, is a far too frequent cause of failures. The tendency to slight the job is almost universal. A rivet or a bolt is left out, with consequent increased strain on those which are actually put in, a forging does not fill out the pattern, or the metal is burned, or a weld is defective. No doubt many will claim that inferior or insufficient compensation is the most fruitful cause of poor quality of work at the hands of those who, in our industrial system, play the part of hewers of wood and drawers of water. But the experience of the last few years has not seemed to confirm this view. If this was the real explanation it would seem to follow that voluntary increase in wages would bring an increase in efficiency. In fact, the increase in efficiency following voluntary increases in wages has been most disappointing. We must apparently look further for the real reason for poor workmanship.

The method of compensation for work performed has a direct and most important influence on the quality of service rendered. I refer especially to the

*Presidential Address delivered before the Am. Soc. Test. Materials, June 29.

piecework system in those places where it is applicable. This stimulates output at the expense of quality, and it is not at all strange, perhaps, that after constructions have found their way into service, we should not infrequently find evidences of the haste, the slurring over, and the inferior workmanship which these methods have necessarily done so much to stimulate. I am not at all prepared to suggest any substitute for them, and am, and have been for many years, an advocate of them from the standpoint of successful management; but it is folly for us to close our eyes to the fact that the piecework and other successful output methods of compensation are antagonistic to quality of work, and that, despite all our efforts to the contrary, they may justly be held responsible for some of our engineering failures.

One more phase of the workman problem. Close observers of the modern workman have noticed for some years a growing tendency on his part to manifest less and less interest in his work. *Esprit de corps*, pride in his work, and a genuine feeling of loyalty and devotion to the establishment of which he forms a part are gradually becoming less and less. The allegiance of the workman, under the influence of the ferment and agitation which now pervades our whole industrial system, is gradually passing over, in a measure at least, to the labor organization. The effect of this transfer of allegiance on the quality of the work performed needs no elucidation.

Third, it is evident that the engineer who makes or finally decides upon the design of any structure carries a heavy load of responsibility. He is first in the field and practically tells all who follow what is to be done. He must decide not only the kind of material that is to be used, but also the amount or sizes, and how it shall be disposed. His realm embraces every kind of structure, from the foundations of a bridge or building to the most minute details of a locomotive or car. His knowledge of the properties of materials must necessarily be broad and comprehensive, and the field is so enormous that there are naturally numerous specialists. The engineer who makes the design labors under two very serious difficulties. First, it is not possible, many times, to compute the strains to which the whole or parts of the structure will be subjected. He, perhaps more often than any of us, is at the end of his knowledge, and if failure due to defective or faulty design comes, he deserves more sympathy than anyone else involved.

But the designer labors under another serious difficulty. He is often overruled and prevented from doing what his judgment prompts him to do, in the interests of safety, by those who control expenses. The construction he would like to use costs more, and the management for economic reasons demands something less expensive.

Fourth, unfair treatment. As already indicated, there is a natural disposition on the part of each of us to relieve ourselves from blame and put the fault on someone else, and there is no field of parcelling out deserts among those involved in failures, and the responsibility therefor more fertile than this one of unfair treatment. Far be it from us to say that unfair usage is not many times a legitimate explanation of failures.

There is, however, another phase of this part of our subject. Unfair treatment is very much broader than the obvious misuse of a bridge or of a moving vehicle. The materials entering into a structure may be unfairly treated. If the calculated strains are too high, or, what amounts to the same thing, too low, a factor of safety is employed, materials are unfairly used. Still further, where a structure is a composite it may, and undoubtedly does, often happen that the elements making up the composite are unfairly treated, as when, for economic reasons, not enough money is spent to properly install the structure. For example, a steel rail called upon to do its work supported by too few ties, insufficient ballast, and a badly drained sub-grade, is unfairly treated. Moreover, the state of repair in which structures are maintained is clearly an element in their fair treatment. If not enough money is spent in repairs, and parts become weakened by decay, corrosion, or wear to such an extent that failure results, it is entirely obvious that the failure must be attributed to unfair treatment.

But perhaps enough has been said in analysis of the causes of failure. Let us now devote a few moments to precautions which may be taken with material and workmanship in the interests of safety; and to a consideration of what should be our mental attitude toward design and unfair treatment. And first as to workmanship. Under present conditions the necessity for close supervision is evident. Managing men everywhere recognize this necessity and are employing all means at hand to secure it.

Second, with regard to material. It is difficult for us to see how anyone who is responsible for safety in structures dare at the present time put material into these structures which has not been bought on carefully prepared specifications, and which, before acceptance, has not been rigidly inspected and tested.

Third, bad workmanship and bad materials can apparently be so controlled as to secure safety by sufficient supervision and by having proper specifications, with rigid inspection and test. But how about the unfair treatment of materials, or the structures made from them?

Fourth, what shall we say of the engineer who makes the design? The truth is, he is often using materials in construction without sufficient knowledge. There is crying need for experiment. Testing machines, adequate to cope with some of the problems which now confront engineers, do not exist. We are increasing sizes and constantly building larger structures. If the test of service gives a failure, it simply proves that our guess as to the increase needed was wrong; and if the test of service shows freedom from failure we still do not know that we have used material wisely and economically. The factor of safety everywhere is largely a guess. The late A. L. Holly, one of the brightest mechanical engineers in this country twenty-five years ago, used to speak of "the ridiculous factor of safety, one-half of which is a factor of ignorance." We cannot help feeling that no better use could be made of some small fraction of the millions that have been accumulated by individuals in connection with our great industries during the past half-century than in the establishment of a Bureau of Engineering Research.

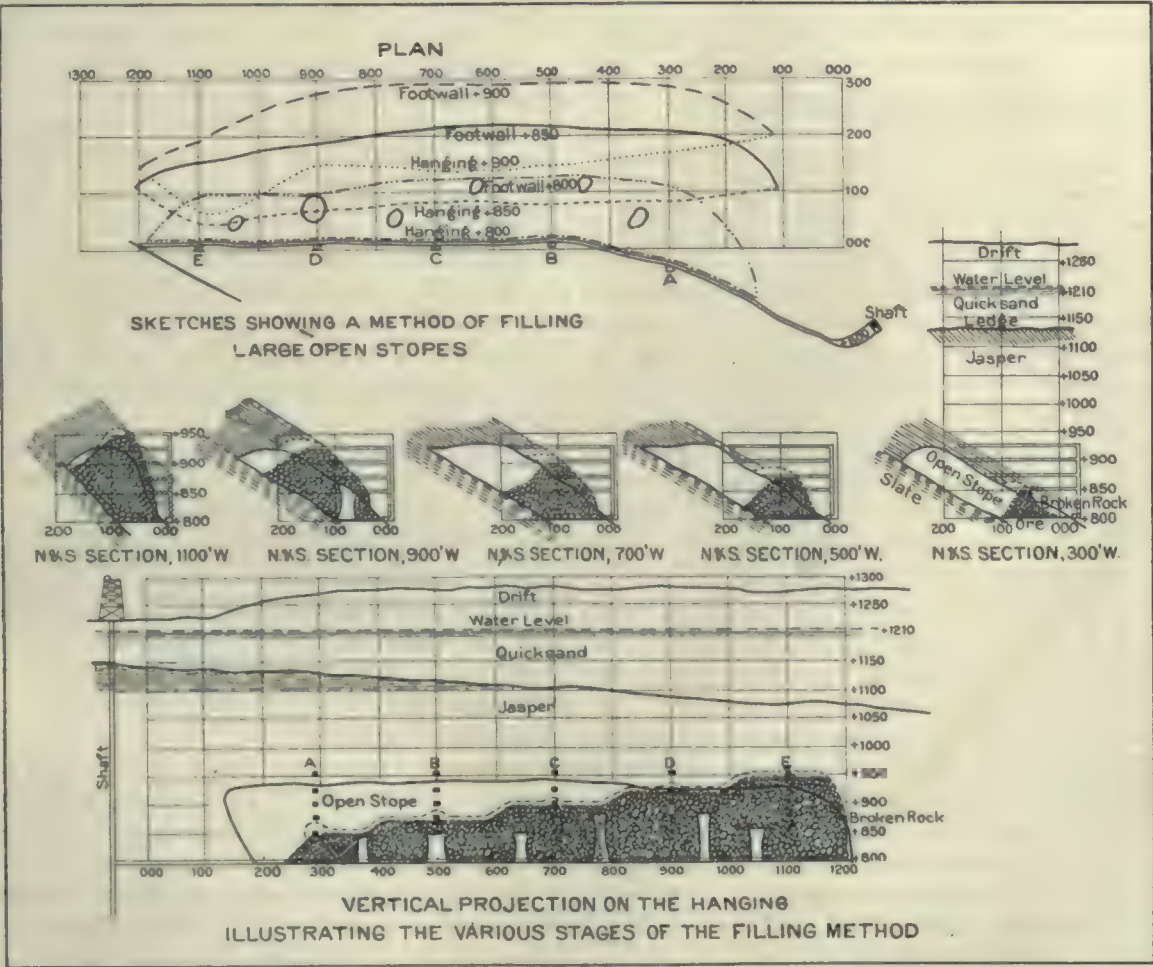

CHANGE OF METHOD IN MINING SOFT ORE.

Written for the MINING AND SCIENTIFIC PRESS
By STUART RHETT ELLIOTT.

The mine which is here described was originally laid out and worked on the square-set room-and-pillar system, the general plan being to make the rooms and pillars each three sets or 21 ft. wide. On the upper levels, however, the ore was mined in open stopes without timber. With the exception of a few small pillars which had been left to support the capping, these stopes formed a great open space, 750 ft. long, from 75 to 150 ft. wide, and from 75 to 250 ft. high, extending up the foot-wall at an angle of about 30 degrees. The mine had been worked on this plan for about fifteen years, when it passed to other interests. At

levels, by what is known as the caving system, no ore is left to support the capping, and the loss is small. The new management decided to adopt the caving system.

It was not thought advisable to open sub-levels directly below this large open stope without filling it. There was great danger that large pieces or slabs of rock falling from the hanging might suddenly crush the working places. Also it was feared that, if a sudden cave occurred over any part of the large open stope and ran a hole to the sand, the quicksand would flow rapidly to all the lower levels, blocking the means of escape for the men, and endangering their lives. Even assuming that such a cave could occur without loss of life, there would still be great chances of serious damage to the mine. The pumps would be

this time most of the available ore in the rooms had been removed, and it became necessary either to open additional levels and continue the original system of mining, or to attack the pillars. The latter alternative was decided on.

The general conditions were quite unusual. Above the rock-surface the sand varied in depth from 125 to 200 ft. The water-level was at 75 ft., making the thickness of quicksand from 50 to 125 ft. The original operators did not think it advisable or practicable to remove enough of the ore to allow the capping to break. It was thought that the quicksand would run into the mine, and that the volume of water which it would be necessary to pump would involve too great an addition to the cost. Under the original plan it was necessary to leave at least 50% of the ore in the mine. By mining the ore in sub-

cut out by the sand, which in all probability would completely fill the greater part of the rooms and drifts below 480 ft., and might even get into the hoisting shafts, in which case the expense of re-opening the mine would be heavy. If the sand got into the rooms, it would not be practicable to leave it there, as in future operations it would become mixed with the ore and greatly decrease its value. In starting the caving system it was therefore necessary in the first place to get a considerable thickness of filling into the large open stope. It was decided to obtain this by blasting rock from the hanging. It was thought that if the open stope could be nearly filled, all danger from quicksand would be avoided, because in case of a cave the broken rock would act as a filter, allowing the water to drain through but holding back the sand. Again, by filling

the open stope, the distance through which the capping could fall in case of a cave would be greatly decreased, and the cushion would deaden the shock, thus diminishing the danger of an air-blast, which might do serious damage to the drifts and even to the shafts. As soon as the pillars were completely surrounded by broken rock, extending up to the hanging, it would be possible to safely remove them by raising from a lower level.

The following is a brief description of the method used in filling the large open stope: from a drift which followed the hanging on the 480-ft. level, vertical raises were put up at intervals of about 200 ft. Each of these raises was stopped at approximately the extreme height of the open stope on the foot. They were made as small as practicable, as only a small amount of rock had to be handled through them. From the raise farthest away from the shaft, at a height of about 50 ft. above the main level, a small drift was driven toward the foot-wall. In order to avoid the possibility of suddenly holing into the open stope, the limits of which it was impossible accurately to survey, long holes were kept ahead of the breast. When within about ten feet of the stope, a number of holes were fanned out from the breast of the drift. By blasting these holes the drift broke through into the stope. The machine was then set up about ten or twelve feet from the end of the drift. From this one point numerous holes were drilled, up and down, and right and left, their general direction being toward the open stope, and their angle with a vertical plane passing through the centre of the machine and parallel with the general direction of the stope, being about 45 degrees. When these were blasted the hole made was conical in shape. This operation was then repeated, the length of the drift being decreased, and the work getting closer to the raise. The pile of broken rock gradually increased in height until it reached the elevation of the floor of the drift. The operation of drilling and blasting was continued until the rock ceased to roll down and began to pile up in the drift. The top of the pile of broken rock was then leveled, and the machine set up a few feet to the west of the line of the drift and close under the hanging. From this position long holes were drilled, inclined downward and in the general direction of the length of the stope. When these were blasted the pile naturally increased in length to the west. The operation was continued until the pile reached about 100 ft., or half the distance between the raises. Going east, working in the same way, this pile also finally attained a length of about 100 ft. The elevation of the first drift to connect with the stope was naturally determined by the distance between the raise and the stope on the main level, and the angle of the hanging side of the stope. The work of blasting off the bottom of the drift could not approach so close to the raise as to endanger it, as it had to be used as a traveling road for similar work at higher elevations. Next, a second drift was driven 25 ft. above the first, and in the same direction, until it also holed into the stope. The same operation, described for the first drift, was carried out in this also, and afterward in other drifts, at still higher elevations. As the rock

when broken occupied considerably more space than when solid, a point was reached when the broken rock ceased to run into the open space. But there remained a certain area next the foot-wall which could not be filled with safety to the men. When it became no longer possible to break rock by working from the first raise, exactly the same procedure was repeated in the next raise to the east, or 200 ft. closer to the shaft.

Great care had to be taken to protect the men. After each blast the rock was well trimmed and all loose pieces taken down. It was not necessary for the men to go far out into the stope where the back was a great distance above their heads. In fact, they were instructed always to keep so close to the hanging that they could touch it with their hands. By following this rule they would be in little danger from small pieces which might slab off. The men were also instructed to take no chances, and to leave their work and go to a place of safety when the rock was continually dropping from the hanging. It was not thought advisable to work a number of gangs on this filling at the same time. For safety it was thought best to start at the west end, and gradually work toward the east. In the breaking of the filling the hanging was still further undercut, and the chances of its caving were increased. The only real cause of anxiety was the chance of a cave occurring before the open stope could be sufficiently filled.

After working continually for two and a half years the stope was finally filled, and during this time no one was injured. Three months later a cave occurred, making a hole at the surface over 300 ft. diam. Anticipating the extra flow of water, the pumping capacity had been doubled, so that it was possible to handle about 2200 gal. per minute. The flow was so great for two days that it was necessary to replace the skips by bailers, which had been kept at the shaft in case of need. After the first few days the amount of water decreased rapidly. Not a pound of sand came into any of the drifts or working places of the mine. There was absolutely no damage done in any way.

As soon as there was a sufficient thickness of broken rock over any part of the open stope, sub-levels were started below. As the filling increased in length, it was possible also to increase the length of the sub-levels. The men mining the ore were safe, except from a sudden cave of great extent, which might close the working places. It is generally believed that extensive caves invariably give ample warning. The well known signs were closely looked for. There were several small caves which did not run holes to the surface. No chances were taken, and the men were not allowed to go into the mine until the stope again became quiet. As the ore on the sub-level directly below the broken rock was mined, the floor was well covered with lagging and the rock was drawn down. Before the cave occurred, the ore on the west end of the old stope had been mined for a depth of 50 ft. below the original floor. At the present time there is a large area over which the cap rock has been broken, and as the ore is removed the entire area slowly settles from the surface.

MEXICAN MINING LAW.

Translated by COURTENAY DE KALB.

On January 1, 1910, it is expected that a revised mining law will go into effect in Mexico. The bill has passed the Chamber of Deputies, and will be considered by the Senate at its session in September. The following is a translation of the first chapter.

CHAPTER I.**MINING PROPERTY AND ITS CHARACTER.**

Article 1. Property under direct dominion of the Nation, and subject to the dispositions of this Act comprises: (1) Formations of all inorganic substances which in veins, beds, or in masses of whatever form constitute deposits whose composition is distinct from that of the country rock, such as those of gold, platinum, silver, copper, iron, cobalt, nickel, manganese, lead, mercury, tin, chromium, antimony, zinc, and bismuth; those of sulphur, arsenic, and tellurium; those of rock-salt, and those of precious stones. (2) Placers of gold and platinum.

Art. 2. Exclusively private property pertaining to the owner of the soil comprises: (1) Formations or deposits of combustible material under all its forms and varieties. (2) Formations or deposits of bituminous materials. (3) Formations or deposits of salts which effloresce upon the surface. (4) Sources of water, superficial or subterranean, subject to disposition according to the common right and special laws regarding waters, without prejudice to the restrictions of Article 9. (5) Rocks of the earth and materials of the soil, such as slate, porphyry, basalt, limestone, and earths, sands, and clays. (6) Bog iron ore, and 'float' iron ore, and stream tin, and ochres.

Art. 3. The provisions of the Civil Code of the Federal District, relative to common property and its division, are applicable to mining property in all particulars not inhibited by this present act.

Art. 4. The unit of mining property is denominated a *pertenencia*, and it is a solid of indefinite depth, limited in the earth by the four vertical planes corresponding to the projection of a horizontal square of 100 metres on each side. The *pertenencia* is indivisible as regards all the acts and contracts that affect possession.

Art. 5. By 'mining estate' (or 'mining property', *fundo minera*) is understood the *pertenencia* or group of contiguous *pertenencias* conveyed by original title or by title transferred and derived from the original.

Art. 6. When on locating a mineral property (or estate, *fundo*) it may not be possible, on account of adjacent mines, to reduce it to integral *pertenencias*, the portion so irreducible will be denominated a *demasía*, considering it, for all legal purposes, to be composed of as many *pertenencias* as there are hectares (each hectare equals 2.47 acres) comprised in its horizontal projection, and the fraction of a hectare which may result will be considered as one additional *pertenencia*. When the irreducible portion may be less, in its horizontal projection, than one hectare, it shall also be called a *demasía*, and shall be considered, with regard to legal effects, as one *pertenencia*. The Regulation (that is, the explanation of mode of applying the law, to be issued later by the Department of Fomento) will determine the form and limits in which it shall be necessary to locate the *pertenencias* and *demasías*.

Art. 7. The owner of a mining property has the right to extract and avail himself of any or all of the substances enumerated in Article 1 which may be encountered on the surface or in the subsoil of the mineral property.

Art. 8. Mining operations may not be extended beyond the limits corresponding to each mining property (*fundo*) as set forth in the title, even when the boundaries consist of territory open to location.

The translation of the entire Project of Mining Law, in pamphlet form, can be obtained from the MINING & SCIENTIFIC PRESS. Its length prohibits publication in the paper. Price 50 cents.

Art. 9. To the owner of a mining property pertains the use and advantage of the waters which drain into the interior of the workings; in consequence he is empowered to extract and dispose of them, together with all the substances which they may contain in suspension or solution. He may not, however, claim any indemnity when said waters weaken or diminish by reason of the unwatering of other mining properties. When the appearance of waters in the interior of the workings may bring about the extinction or diminution of neighboring water-flows, the proprietors of those will possess the right to recover the waters which pertain to them, but without depriving the owner of the mineral property of the waters which he needs for the conduct of his industry, nor shall they be able to require any indemnification from said owner. The transference or loss of property right in a mining estate (*fundo*) involves respectively the use and advantage of the water which is encountered, or which issues in the interior of the workings.

Art. 10. The mining industry is a public utility; in consequence, the owners of mining properties have the right to expropriate under those circumstances and conditions which this law indicates.

Hydraulic Mine Equipment for Panama.

An agent of the Panama Canal Commission was recently in California studying hydraulic-mining methods with the intent to introduce economies in handling material on the Isthmus, if possible. The decision to adopt certain hydraulic methods has been reached, and the Commission is now asking for bids upon specifications which can be obtained from the Assistant Purchasing Agents of the Commission, who maintain offices in New York, Chicago, Boston, New Orleans, San Francisco, Los Angeles, and practically all of the larger cities in the country. The total amount of material to be handled is 8,000,000 cu. yd. We reproduce below an extract from the specifications:

"METHOD OF OPERATION.—Centrifugal dredging pumps will be sunk, by stages, in the prism to be excavated, until rock is reached, and the sedimentary material mined with monitors and sluiced to the dredging pumps. Salt water supplied through pumps will be used for mining and sluicing. As there are only 3000 electrical horse-power available, and it is not considered advisable to increase the electrical plant, the available power will be utilized for operating the dredging pumps only and the remainder supplied by an oil-burning steam-plant. The method proposed consists of a central pumping station to be operated by steam and provided with four or more high-duty pumps having a combined capacity of 30,000 gal. per min. through 3600 ft. of main. Each of the three lifting units will consist of a centrifugal dredging pump with belt-connected motor capable of handling 10,000 gal. of water per minute, together with the resulting debris. In short, the central pumping station must supply sufficient water for three units consisting essentially of the following, per unit: first, two monitors set on branch lines; second, one centrifugal dredging pump with belt-connected motor; third, all necessary pipe-lines, including connections and fittings.

"CAPACITY OF EACH UNIT.—Each of the units shall be capable of excavating and disposing of 300 cu. yd. of solid matter per hour, based on using 10,000 gal. of water per minute, or about 10 cu. ft. of water per cubic foot of material handled. Each dredging pump shall be capable of handling the above 10,000 gal. per min., together with the excavated material, as specified hereafter."

CENTRAL PUMPING STATION.—Bidders will submit a separate price for substituting reciprocating steam pumps, having the same combined capacity, for the centrifugal pumps and engines specified for the central pumping station.

It is the desire of the Commission to obtain, within reasonable expense, a pumping plant that is best adapted to the work to be performed, including economy in operation, and to this end any bidder who submits a proposition for the plant herein specified, together with alternative bid 'A', may also, in addition, tender proposals on specifications of the same which his experience may suggest.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS.

HANDBOOK FOR FIELD GEOLOGISTS. By C. W. Hayes. Pocket size, flexible back, pp. 159. John Wiley & Sons, New York, 1909. Price \$1.50.

The first edition of this book was prepared as a guide to members of the U. S. Geological Survey, but proved to be in such demand that Mr. Hayes re-wrote the work and adapted it to general use. It is a valuable little hand-book and contains just those short practical points which every geologist must learn but no one thinks to tell him till after he has made a mistake. The information is not obtainable elsewhere in anything like the same detail.

STATISTICAL ABSTRACT OF THE UNITED STATES, 1908. Department of Commerce and Labor, Bureau of Statistics. 8vo., pp. 744. Washington, 1909.

This is the thirty-first number of one of the most valuable hand-books published by the Federal Government. The subjects treated include area, natural resources, population, agriculture, forestry, fisheries, manufacturing, mining, patents, labor, transportation, commerce, money, wealth, and many other topics.

WATER SUPPLY INVESTIGATIONS IN THE YUKON-TANANA REGION, ALASKA, IN 1907 AND 1908. By C. C. Covert and C. E. Ellsworth. U. S. Geol. Survey. Water Supply Paper 228, pp. 108. Washington, 1909.

The importance of quantitative data regarding water supply in the northern placer mining regions is recognized by the Government officials, and in this bulletin are maps and tables for the Fairbanks, Circle, and Rampart districts.

INVESTIGATIONS RELATING TO GOLD AND SILVER IN 1908. By J. M. Hill, F. L. Ransome, J. S. Diller, G. F. Kay, D. F. MacDonald, and J. T. Pardée. Pp. 80. Washington, 1909.

An advance chapter from the Contributions to Economic Geology of the U. S. Geological Survey for 1908, containing notes on Gunnison county, Colorado, the Hornsilver district of Nevada, and the Grants Pass, Bohemia, and Cracker Creek districts of Oregon.

SOME DESERT WATERING PLACES IN SOUTHEASTERN CALIFORNIA AND SOUTHWESTERN NEVADA. By Walter C. Mendenhall. U. S. Geol. Survey, Water Supply Paper 224, pp. 98. Washington, 1909.

The map, list of springs, and hints on desert travel make this report of high value to prospectors and others having occasion to travel in the region discussed.

THE FORTY-MILE QUADRANGLE, YUKON, TANANA REGION, ALASKA. By L. M. Prindle. U. S. Geol. Survey, Bull. 375, pp. 52. Washington, 1909.

The accurate topographic and geologic maps, and the brief texts forming this report, will be of high value to all undertaking development in the region.

PRODUCTION OF SLATE IN 1908. By A. T. Coons. U. S. Geol. Survey. Adv. Chapt. Min. Res., 1908, pp. 15. Washington, 1909.

Figures of production, with general notes on the classification and characteristics of slate, by T. Nelson Dale.

BRIQUETTING TESTS AT THE UNITED STATES FUEL-TESTING PLANT, NORFOLK, VIRGINIA, 1907-8. By Charles L. Wright. U. S. Geol. Survey, Bull. 385, pp. 41, Ill. Washington, 1909.

ILLINOIS SOCIETY OF ENGINEERS AND SURVEYORS. Twenty-fourth Ann. Rept. 8vo., pp. 287, Ill. Chicago, 1909.

Coal in Washington in 1908.

The total production of coal in Washington in 1908, as reported to E. W. Parker of the United States Geological Survey, was 3,016,557 short tons, having a spot value of \$6,673,091. Compared with the record output of 1907, the production in 1908 showed a decrease of 663,975 short tons,

or 18.04%. The value declined \$1,006,710, or 13.10%, and the output was the smallest in any one year, except one (1905), since 1903, due to the business depression. The price per ton in 1908 showed an increase over 1907.

The coal mines of Washington gave employment to an average of 5413 men in 1908, a decrease from 5945 men in 1907. The average working time decreased from 273 days in 1907 to 203 days in 1908, but where men work a fewer number of days during the year the intensity of labor may be increased. In the coal production of Washington this is shown by the fact that the average daily production per man increased from 2.27 tons in 1907 to 2.74 in 1908, but because of the fewer number of days worked the total production per man for the year shows a decline from 619 tons in 1907 to 557 in 1908.

Commercial Paragraphs.

The SULLIVAN MACHINERY Co. announces that its El Paso office and warerooms have been moved to 506-8 San Francisco street.

The BALDWIN LOCOMOTIVE WORKS, Philadelphia, has purchased the property, business, and good-will of the firm of Burnham, Williams & Co. and assumed all its assets and liabilities.

THE LUNKENHEIMER Co., Cincinnati, announces that it has recently sold an order for Renewo valves amounting to \$50,000, to the Panama Canal Commission. This is the second large order from the Commission during the past year.

THE CUTLER HAMMER MFG. Co., Milwaukee, Wisconsin, announces that it has purchased the plant, business, and patents of the J. L. Schureman Co., of Chicago, and that it will continue the business, for the present at least, at the old address, 70 West Jackson Boulevard.

The RISDON IRON WORKS, San Francisco, has lately closed a contract with the Nevada Mining, Reduction & Power Co., of Dayton, Nevada, for a 40-stamp mill. The building is to be structural steel covered with corrugated iron. Sixteen Risdon-Johnston concentrators are to be used in the mill.

The WESTINGHOUSE ELECTRIC & MFG. Co. has lately furnished electric equipment as follows for mining properties: six 600-hp. motors for the Washoe smelter of the Anaconda Copper Mining Co., at Anaconda, Montana; turbine plant for the Helena Power Transmission Co., Butte, Montana, supplying Butte mines with electrical energy under 70,000 volts pressure; and the pumping station of the Leonard mine of the Boston & Montana C. C. & S. M. Co., contains five 150-hp. Westinghouse motors direct connected to Nordberg pumps.

Catalogues Received.

CAMERON PUMPS are well illustrated in an excellent little paper, 'The Story of a New York House', which also tells how Adam Scott Cameron built up the business which still carries his name.

The DODGE MFG. Co., Mishawaka, Indiana, has lately published a handsome 104-page catalogue, called 'Twenty-Five Years of Rope Driving'. It is replete with numerous photographs and drawings and contains much that is of interest to all who are concerned with the transmission of power.

THE LUFKIN RULE Co., Saginaw, Michigan, has just issued its catalogue No. 8 in which are listed measuring tapes and rules of every description. A novel and decidedly useful improvement in the method of marking tapes, developed by this company, consists in repeating the number representing the feet at each inch or tenth-foot mark. Hence mistakes of integral feet in reading tapes are almost impossible.

The WESTERN GAS ENGINE Co., Los Angeles, is distributing a pamphlet containing information concerning a test made on a Nix-Frost suction oil gas producer and a Western gas engine. The test was made by William F. Durand, professor of mechanical engineering at Leland Stanford University. The result of this test shows, that with oil costing 75c. per barrel, the cost of fuel amounts to practically ¼c. per brake-house power hour.

EDITORIAL.

ORE RESERVES blocked by the Ray Consolidated Copper Company are now said to be 28,000,000 tons, connections between drill-holes in one month having increased the proved cube 7,000,000 tons. The average copper-content of this ore is $2\frac{1}{2}$ per cent.

ADMINISTRATION of the National Forests involves the useful function of protecting timber from fire. The distribution of the forests in the West brings the fire-patrol within reach of a large part of the private-owned reserves as well. This insurance against devastation amounts to $1\frac{1}{2}$ cents per acre on the National Forests, and falls to nearly half that amount when the total area served is taken into account.

ANNOUNCEMENT is made by the Transvaal Chamber of Mines that the total gold production of the Rand to the end of 1908 has reached the splendid sum of \$1,120,000,000. That brings the Rand to third place in the list of the world's gold contributors, and it possesses a youthful vigor which will lead to ultimate dominance. At the present time the respective totals attained by the rival gold areas are, for California, \$1,511,500,000, and for Australia \$2,366,000,000. To approach these magnificent figures the Alaskans have still a long race to run, the gross output up to the end of 1908 being \$141,535,237. We have yet to hear from the quartz mines of the North, many of which are yielding such results as to promise a brilliant future.

MEXICANS are pleased with the transfer of Mr. Henry Lane Wilson from the court of Belgium to the ambassadorship before the Mexican Government. Mr. Wilson is a trained diplomat, an accomplished linguist, and is favorably known at Chapultepec through his former connection with the Mexican embassy. At the same time comes confirmation that Mr. Charles R. Crane has accepted the post of Minister to China. As a member of the great Chicago house of Crane Company he possesses the requisite commercial qualifications, in addition to his other accomplishments. He is intimately acquainted with the Orient, and speaks Russian fluently, which will aid in dealing with the delicate Manchurian problem.

CONSOLIDATION for the establishment of a trust is likely to entail internal difficulties. This has been discovered by the Western Federation of Miners. The rank and file find themselves in the same position with reference to the management as common stockholders to the board of directors and executive officers of a corporation. The officials at times forget the community of interest that should

make them unselfish administrators for the good of the members of the organization. Thousands of miners have failed to appreciate the need of persistent assessments after studying the financial statements issued by the officers of the Federation. They contrast the difference between their \$3 per diem with a cot in an ill-kept bunk-house, and the creature-comforts enjoyed by Mr. C. H. Moyer in Denver. They reflect upon the equality of condition which is the underlying principle of that socialism which the hard toiler understands, and they fail to see a practical application of it by their leaders. Hence the determined effort now being made by the convention of the Western Federation to oust Mr. Moyer and establish control by an executive committee.

HAWAII, it seems, is still represented in Mexico by a consul general, vice consul general, and various resident consuls. It is true that the 'consul general' has been dead some years, and that Hawaii has been annexed to the United States, but the Department of Foreign Relations not having been 'officially' informed of these facts, maintains the names on its published register. The annexation of Hawaii having been a side issue in connection with other war measures, it was evidently deemed an affair of either the Secretary of War or the Secretary of the Navy, and was overlooked by the State Department. The Government spasmodically awakens to the existence of the 'key of the Pacific' when the Japanese bogey recalls the defenselessness of the 'key'. But Señor Mariscal really ought to be officially informed that the administrative revolution led to the extinction of Hawaiian autonomy.

RAILWAY CONSTRUCTION in the West has gone steadily forward despite the hard times of the last two years. The Chicago, Milwaukee & St. Paul has been completed to Tacoma. The new Hill road from Spokane to Portland has been built, and within the year it is expected that the Western Pacific will be completed into San Francisco. These are all trunk-lines. Many important branches have been completed and others are building. Among these are the west coast line of the Southern Pacific in Mexico, the Northern Pacific from Portland to Tacoma, and the North Coast and Canadian Pacific in Washington. All open new territory and render old mining regions more accessible. They will doubtless greatly stimulate mining. The Western Pacific, with its low grades and substantial construction, should make extensive development possible in Sierra, Plumas, and other isolated mountain counties of California.

RUMORS of political ferment continue to come from Mexico. The adherents of Gen. Bernardo Reyes are active; naturally they desire the election of their candidate for the vice-presidency, and at times their enthusiasm becomes noisy. Such spectacles have been witnessed in the United States; and even England is not so staid but the authorities now and then are compelled to read the riot act. It is not warrantable to take these outbreaks of popular feeling as seriously as do some writers on public

affairs. President Diaz has created a new Mexico; he has given the nation rank among the great ones of the earth; and he has done it in the face of almost overwhelming opposition. Those who have fondly imagined that he was a popular idol, leading a grateful people by the power of love, simply have not known Mexico. It cannot be denied that the Reyistas have taken up a cry which is difficult to suppress. The desire of the Government to limit the freedom of foreign corporations was in answer to a growing demand of the younger generation. The liberal granting of concessions had alarmed them; the fear of great dominant foreign monopolies had taken root in their minds. The efforts of the administration to alter its policy have been met by determined resistance from foreigners, and from a large number of Mexicans whose interests are allied with the alien corporations. Hence it will be seen that opinion is divided, and that the two parties are merely in healthy opposition. There are checks and balances within the domestic political arena that insure stability.

CUBA evidently desires her resources to be better known. Mr. Leon J. Canova, an American, has been made director of a newly established Utility and Information Bureau in the Department of Agriculture, Commerce, and Labor at Havana. He should be addressed by intending investors. This is a step in the right direction. We hope, however, that adequate provision may be made for obtaining as well as giving information. Accurate surveys, topographical, geological, and agricultural, are much needed. General information is now-a-days of small import, and details of value can only be obtained by trained observers. Considering the time and money expended, the geological reconnaissance made by Messrs. C. W. Hayes, A. C. Spencer, and T. W. Vaughan was excellent, but for the solid development of the mineral resources much more extensive work is necessary.

Great Steel Works in Chile.

Chilean enterprise is emancipating that Republic from dependence upon foreign markets for supplies of iron and steel. Americans have been singularly dazzled by the vision of Cathay, a traditional light that has drawn attention away from larger opportunities in the Southern Continent. The foreign trade of South America is immensely greater than that of the Orient, but the United States has permitted other nations to absorb it. Nearly twenty years ago Señor José M. Balmaceda extended to capitalists in this country an opportunity to develop the iron deposits of Valdivia, under contract with the Chilean Government. This contract would have conceded subsidies assuring a substantial profit. Subsequent presidents have sought to enlist the interest of foreign capital, but all efforts in America and England proved futile. Finally the French lent a willing ear, the deposits were investigated, and as a result the stately structures of a great smelter have arisen on the shores of Corral bay, just south of the city of Valdivia. Six Kopper stoves have already been erected, the first blast-furnace is nearly

complete, and a second, with its accessory equipment, has been started. An aerial tramway has been provided to convey the ore to the smelter, a distance of eight kilometres, and charcoal ovens have been built, for it is proposed to utilize the splendid forests of Valdivia, in conjunction with the exceptionally pure ores available, for the manufacture of charcoal-iron. Announcement is now made that the erection of steel works will immediately follow. When it is realized that this undertaking is financed by no less a firm than Schneider & Company, owners of the famous Creusot works, next to Krupp the largest iron and steel manufacturers of Europe, the fact that a new industrial era is beginning in South America becomes apparent. The manufacture of machinery will speedily follow. The great water-powers of the rivers flowing down from the Andes to the Pacific will be developed, and the commercial requirements of the Andean chain of Republics will be locally supplied. The contract under which the Creusot concern has organized the *Compañía Siderúrgica Francesa*, approved by special act of the Chilean Congress, guarantees interest upon the invested capital in return for a stated annual production, secures the payment of a bounty upon the actual output, and grants a concession for the free use of enormous forests for a long period as a source of fuel-supply. The present demand for iron and steel in Chile exceeds 100,000 tons per annum, and that of its neighbor, Argentina, amounts to 700,000. Manifestly abundant warrant exists for establishing these works. The pity is that the people of the United States, trained by more than a century of successful pioneering, should not apply their talents to the development of the virgin resources of South America. The splendid achievements of our capitalists and engineers in Mexico should have encouraged a farther look into the possibilities of Spanish America. It was propinquity that led to our pleasant and mutually helpful relations with Mexico, and while propinquity is the determining cause of many marriages, some of the imagination that has run to waste in flirting with the Orient might have yielded better results if directed toward the South. It is not too late, however; immeasurable opportunity lies open to those who will seek it there.

Clemenceau and the New Industrialism.

France has lost a brilliant leader in the downfall of M. Clemenceau. In the shadow of the Moor the keenest master of men in Europe has met defeat. The unguarded reference to the political maelstrom into which France was nearly drawn through the bungling of M. Delcasse in the Algeciras crisis, was so unlike the inscrutable Clemenceau as to suggest that he must have been irritated by a rising of the Moroccan ghost in a new embodiment. Recent developments indicate that the new prime minister may take up the game at a moment of difficulty. He is likely to meet the German war lord flushed with confidence, with only a puppet-chancellor to convey his orders, and eager to catch at a fair excuse in Africa to divert attention from domestic finances. The retirement of both von Buelow and Clemenceau

while Morocco is convulsed with fresh dissensions, is a menace to the peace of Europe. Skilled men are needed in such affairs. The larger significance of the downfall of the great French statesman lies in the opportunity which it offers to the socialists. They welcome his defeat with joy. The sullen chanting of the 'Internationale' during the recent Government employees' strike had no terrors for Clemenceau. He met the organized workers with an irresistible weapon, the power of individual self interest. A combination among the strikers carefully made to-day was broken on the morrow through the halting of erstwhile leaders—and all France knew that the hand of Clemenceau had been outstretched. He was in some ways more subtle than Richelieu. The famous Cardinal worked through infinitely complicated subterranean channels, but he seldom appeared openly as an actor in the dramas which he controlled. M. Clemenceau, on the other hand, trusted largely to his knowledge of human nature to gain his ends. Characteristic was his treatment of the leader of the wine-growers' revolt nearly two years ago. A simple peasant, filled with indignation over the ruin of legitimate wine-making by the manufacturers of the artificial product, he discovered his power to influence men by a happy speech in the streets; he electrified the South of France by his simple oratory; the wheels of government became blocked; even prefects fell from power; and the struggle was brought to the very gates of Paris. The prime minister sent for the popular peasant leader, in whom the socialist party had come to place hopes of large success; he greeted him warmly, complimented him, praised him, assured him of sympathy for the working man, commiserated his poverty—"Poor fellow! You have not even means with which to take lodgings at an inn; here, take this hundred franc note to make yourself decently comfortable in Paris, and come to see me again day after tomorrow." He took it, and the next day the fact was flashed to every Canton in France; the leader of the peasants had disowned the badge of poverty; he was ready to take succor from the rich; his virtue had been drawn by a single hundred franc note. Thus the idol fell, and the peasants, deprived of their leader, followed the line of least resistance back into their routine of hardship. But France was saved from present trouble; mob rule was averted; the course of social evolution was not marred by revolution.

The downfall of M. Clemenceau is likely to exert a powerful influence on the labor movement throughout the world. France is on the verge of industrial transformation which will out-Belgian the Belgians. That great changes are inevitable may be conceded; but should they be precipitated suddenly, a devastating crash would assuredly follow. Precisely such a moderating genius as M. Clemenceau was needed to guide the State through these dangerous straits. That he should have been harassed into indiscretion is an impressive instance of fallibility in a great man; still more impressive is the fact that a ministry should fall because of a simple reference to a past event which all men knew but wished to forget. The pendulum that controls the affairs of nations swings from a tenuous thread.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. PARKE CHANNING is in London.

J. VOLNEY LEWIS is in Durango, Mexico.

E. C. HOLDEN is at White Plains, New York.

ALBERT ROBERTS is at Lake Tahoe, California.

H. E. WEST has left El Oro, Mexico, for London.

WILLIAM FORSTNER has returned to San Francisco.

ELWYN W. STEBBINS is at Nevada City, California.

C. S. HERZIG is expected in London, from Nicaragua.

F. L. BOSQUI is on his way from London to San Francisco.

W. B. WINSTON has returned from Oroville to San Francisco.

H. KILBURN SCOTT has returned to London from Nova Scotia.

FORBES RICKARD has been examining mines in Bingham canyon, Utah.

S. H. BROCKUNIER has returned to Wheeling, W. Va., from San Francisco.

CHARLES M. TAYLOR, of Greymouth, New Zealand, was in San Francisco.

L. R. GAY has been inspecting prospects in Sinaloa for W. A. PRICHARD.

R. GILMAN BROWN has returned in excellent health, from West Africa to London.

W. J. LORING, on his return from West Africa, is laid up, in London, with malaria.

HENRY S. WASHINGTON has returned from Bahia, Brazil, from a six months mine examination.

BENZO KATSURA, professor of metallurgy in the Tokio Imperial University, was in San Francisco.

JOSEF BAYER left by the S. S. *Ella* for Nicaragua, to resume his post at the La Leonesa mines.

E. R. PEMBROKE, former manager of the Boston & Pioche Mining Co., is in Montana examining mines.

JAMES H. MCCREERY, president of the San Felipe Mining Co., is now at the mines near Etzatlán, Jalisco.

W. WIDDOWSON has become superintendent for the Enterprise Mining Co., at Cooney, Socorro, New Mexico.

M. S. GRIFFITHS is engaged as general superintendent of O. y T. Braniff & Co., at Doctor, Querétaro, Mexico.

FRANK HAWKER of Mexico City has been in Tepic, Mexico. He will erect the new mill at the Tenamache mines.

W. H. COGHILL, professor of metallurgy in the Northwestern University, Evanston, Ill., was in San Francisco.

D'ARCY WEATHERBE, having recovered from a severe attack of pneumonia, returns to Rio Tinto at the end of July.

JOHN A. DRESSER and J. W. BELL, of McGill University, Montreal, inspected the Norton Copper Mine, at Suffield, on June 21.

HENRY F. A. RIEBLING has resigned as metallurgist for the Gold Run Mining & Tunnel Co., Wallstreet, Colo., and will reside in San Francisco.

J. M. NICOL has completed the designs for the water-power and pump-slucing plant for the Trinity River Mining Co., and is now in Mexico.

Obituary.

ISAAC RICHARDS, one of the best known Cornishmen of the older generation, died on July 3 at his home at Tavistock, Devonshire, at the advanced age of 87. For 46 years he was connected with the Great Devon Consols mine, in East Cornwall, from 1878 until his retirement in 1891 being general manager. This mine was once a large producer of copper and arsenic. Captain Richards designed the plant for the recovery of copper from the mine-waters, and also erected the arsenic refinery. His son, Thomas Richards, is well known as the manager at the Nundydroog mine, in India.

ARIZONA.

COCHISE COUNTY.

The Tombstone Consolidated Mining Co. cut a rich body of ore in the Tombstone mine. A station is being cut on the 1000-ft. level and new pumps have been ordered. William F. Staunton is manager.—It is reported that the Barrett mine, six miles northwest of Gleeson, is to be re-opened.—At the Heffern mine the shaft is being sunk below the 325-ft. level and a cross-cut run toward the contact from that point.—Samples from the ore recently cut by the adit on the Comanche Chief claim at Paradise assayed 17% copper, 24% lead, 3 oz. silver, and \$1 gold per ton. A winze is to be sunk on the ore and a cross-cut run between it and the old shaft.—J. W. Miller, of El Paso, has secured an option on the Scanland group in the Paradise district. The surface work on these claims has opened several copper-bearing veins.

GILA COUNTY.

The drift from the 600-ft. level of the Superior & Boston is in ore that assays 14% copper.—The shaft on the McEwen & Davidson claims, three miles northeast of Globe, cut a 6-ft. vein of copper glance at a depth of 40 ft.—The Sullivan shaft of the Cordova Mining Co. opened a body of 3% copper at 195 ft. This property joins the Miami, and it is thought to have a continuation of the Miami orebody that was cut at a similar depth.

MARICOPA COUNTY.

The St. Francis Gold Mines Co. is constructing a road from the Keystone camp to its mine. The company has sunk a 100-ft. shaft and driven about 800 ft. of cross-cuts on the property, opening a 2-ft. vein that assays \$15 per ton.

MOHAVE COUNTY.

The Desert Power & Water Co. has completed its power plant and is supplying Kingman, the Tom Reed, and Gold Roads mines with electric power. The Gold Roads mill of 40 stamps, with a tube-mill for re-grinding, and a cyanide annex, is nearly complete, and in a short time will be handling 200 tons of ore per day. The Tom Reed mill has installed 20 new stamps and will be running shortly.

SANTA CRUZ COUNTY.

It is understood that the Calumet & Arizona Mining Co. has secured an option on the Three R group in the Patagonia district. Considerable development work has been done on this property, which is owned by R. R. Richardson, and some ore shipped to the smelter.

YAVAPAI COUNTY.

The Shylock mine of the Central Arizona Copper Co. is to be re-opened. A 50-hp. hoist, pumps, and Temple drills have been purchased and will be installed at the mine shortly. On the 500-ft. level the work will be blocking out the ore, and at the 600 sinking will be resumed in the shaft. The old road from Grapevine is being re-built, and a contract has been let to the Arizona Power Co. to extend its lines to the company's camp. J. B. Cleaveland is superintendent.—The shaft of the Mt. Elliot Consolidated Mining Co.'s Dividend mine, near Chaparral, cut a vein that assays \$70 per ton at a depth of 500 feet.

CALIFORNIA.

ELDORADO COUNTY.

John McLean and George Baldwin have secured a lease on the Golden State mine and have commenced opening the old workings.—Williams & Costello have cut a 10-ft. vein on the Gold Crown property that mills about \$10 per ton.—Fred Kubie and Lin Arnold have bonded the Last Chance mine near Pilot hill and are installing a 2-stamp mill on the property.

MARIPOSA COUNTY.

Smith & Arnold, operating the Peach Tree and Panoche mines for the South Fork Mining & Power Co., have just completed a survey for a power-plant on the south fork of the Merced river.

NEVADA COUNTY.

The adit at the Gaston mine was driven 188 ft. during June. From the upper workings enough ore is being taken to keep the 10-stamp mill running. E. J. McCutcheon is manager.—Keller & McMillan, who have been opening the Yellow Metal mine near Bowman's dam, have interested H. H. Jack in the property, and the latter will finance the building of a 10-stamp mill.—A new compressor has been ordered for the Golden Gate mine and will be installed in a few days. The 10-stamp mill is running on good ore. W. P. Martin is superintendent.—The drift on the Blue Bell group of the Gold Bank Mining Co., near Maybert, is in 120 ft. on a 14-ft. vein. Surface samples from two ore-shoots on the property assayed between \$20 and \$40 per ton.

PLACER COUNTY.

The 1600-ft. adit at the Bishop mine has opened the Slab channel and a drift run along the bedrock. E. M. Threlkeld is president.—The Bisset brothers have taken \$1600 out of two pockets from their property on Iowa hill, near Colfax.—The Home Ticket mine has been closed by a strike, the men refusing to work underground with Chinamen. W. S. Fletcher is in charge of the mine.

SAN BERNARDINO COUNTY.

The Oro Belle shaft is in low-grade ore at a depth of 280 ft. A station will be cut at the 300-ft. level and drifts started from that point. The east and west cross-cuts on the 100-ft. level and the east cross-cut on the 200 have opened low-grade orebodies.—A new hoist is to be installed at the Dayton shaft of the Oro lease of the Big Chief Mining Co. at Hart, and sinking continued to the 500-ft. level. William L. Foster is manager.—The equipment for an additional 60 stamps has been purchased by the Gold Mountain Mining Co. in the San Bernardino mountains and will be placed in the mill in a short time.—At the Morse-Kizer mine at the mouth of Silver creek a 3-stamp mill is being constructed.—Dave Wright is erecting a 5-stamp mill on his property at the head of Silver creek.—The Acme Mining Co. is installing a 5-stamp mill at the mine 20 miles south of Hart.—At the Vontrigger mine of the California Gold & Copper Co., 18 miles south of Hart, the copper leaching plant is rapidly nearing completion. There are 30,000 tons of ore piled on the dump. A. H. Cram is manager.—The 10-stamp mill at the Vanderbilt mines is running steadily. Ohio capitalists have an option on the property.

SHASTA COUNTY.

Work is to be resumed on the Arps claims near Copper City.—Furnace No. 3 at the Mammoth smelter has been started for a short time while No. 5 is being repaired.—Monohan & Maxwell are shipping regularly from their lease in the Uncle Sam mine to the Mammoth smelter.

SIERRA COUNTY.

George Wingfield, the Nevada mine operator, has bonded the Pacific gravel mine near Port Wine. A bedrock adit will be started shortly to tap the channel, two miles of which is on the Pacific ground.—The drift on the vein of the Rainbow mine has opened another rich pocket of ore that is said to be higher grade than the first discovery.—Lutz, McMaha & Gambrina have obtained an option on the Rosasco property, three miles west of Downieville. The vein is on a serpentine contact and has been opened by a number of surface cuts showing it to have an average width of about 3 ft. The shaft and two adits on the property will be cleaned out and work resumed in each.—The old North Fork gravel mine north of Forest City has been bonded to George F. Stone and associates. The road to the mine is being re-graded and lumber and supplies hauled to the mine.—A cross-cut is being driven from the bottom of the shaft to the vein on the Bixby property. A surface adit opened a good shoot of ore carrying a large amount of arsenical pyrite. At the Omega the gravel averages about \$7.50 per car. Charles Brown is superintendent.—Fred W. Kuhfield is opening the Alpha claims, three miles north of Forest, and the Florence and Florence Extension, on Oregon creek, for a Los Angeles company. On the Alpha an adit is being driven that will give about 200 ft. of backs.

—H. Eckart has secured a bond on the New Jersey gravel mine, which contains a portion of the Omega channel.

TRINITY COUNTY.

The Morris brothers received \$400 per ton for a recent shipment of ore from their Spring Gulch property.—A 12-in. vein has been opened on the Gold Chest property of J. H. Boyce and associates.—The 400-ft. cross-cut has opened a 3-ft. vein on the Alaska mine. The property is owned by F. Junkans and P. Leulla.—The vein in the Mammoth mine of the Oversight Mining Co. has been cut on the lower level and a drift is being run to open the ore-shoot worked in the level above. A. H. Wolfe is in charge of the work.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work is to be started next week in the construction of the new 50-ton mill for the Griffith Mining Co. The building will be situated near the portal of the Doric adit on Saxon mountain. The mill is to be equipped with a chemical-electro process, which is the invention of J. L. Malm, of Denver. A similar plant is to be built at the Stanley mine near Idaho Springs.—The holdings of the Democrat Mtn. M. T. & T. Co. were sold last week by the trustee in bankruptcy, F. Bromley, the property being purchased by H. O. Marcy, of Boston, the consideration being \$39,600, including costs. It is stated that during the next 30 days work will be resumed upon a large scale, as a company is now in process of organization.—The Geneva Ext. M. M. T. & T. Co., operating in the Peru district, has started a new cross-cut. It is intended to install a compressor and electric drills during the summer. E. K. Cass, of Georgetown, is manager.—G. J. Hite has started work upon the Bloating Bond group of claims, on Columbia mountain.—Work has been resumed upon the Stemwinder mine and a fair tonnage of sulphide ore broken from a streak of ore that is from 8 to 12 in. wide and assays from 275 to 324 oz. silver per ton. J. M. Shaller, of Denver, is manager.—E. F. Byers, leasing on the Pelican vein, shipped 100 tons of lead-zinc ore last week. The product was sent to the Mendota mill for concentration, and after reducing 5 to 1, the concentrate was sold for \$65 per ton. A vein of ore 3 ft. wide has been uncovered by Weaver & Co., leasing on the Lamartine. A shipment was made last week of 100 tons that was settled for on the basis of \$35 per ton. Occasional bunches of ore are found that mill as high as 19 oz. gold per ton.—The Katie Emmett mine on Cascade creek has been taken under lease by Ford & Co., of Idaho Springs, who have leased the Weeden 5-stamp mill. The entire dump is to receive treatment.

Georgetown, July 14.

GILPIN COUNTY.

The Incidental Gold Mining Co. has secured an option on the Incidental mine from the Pewabic Consolidated Mining Co. and the adjoining Hall property. The Hall shaft has been unwatered and a drift started from the 200-ft. level to connect with the Incidental workings. The smelting ore is being stored on the dump and the milling grade shipped to the Fifty mill at Blackhawk. W. L. Stull, of Russell Gulch, is manager.—During the past week a carload of concentrate was shipped to the Argo smelter from the Perigo mill.—An ore-shoot assaying \$14 per ton was opened on the Hilltop property in South Moon gulch. John Hilton owns the claims.—In the Sleepy Hollow mine 80 ft. of stoping ground has been opened on the 300-ft. level that averages 3 ft. in width. A streak of smelting ore varies from 6 to 20 in. wide and assays \$30 per ton, while the milling ore runs between \$8 and \$9 per ton. On the ninth level the smelting ore assays \$50 per ton, and on the eleventh level the ore recently opened averages the same. Floyd Weed is superintendent.

GUNNISON COUNTY.

A large body of iron ore is being opened near tank 7, on the west side of Marshal pass, to supply the Pueblo Steel Works with an ore for the manufacture of pig-iron.—The Vulcan Sulphur Co. has placed 35,000 shares of its stock on the market to raise money for further development. There are 10,000 tons of ore blocked out in the mine, and the re-

tort and refinery have been started for the season's run. Fred Russell is manager.—John F. Pearson shipped a \$1200 retort to the Denver Mint from the Gold Links mine at Ohio City.—Emil Peterson is opening some rich ore in the Victor mine at White Pine.—A new hoist is being installed at the Morning Star mine near White Pine. The mine is shipping lead-zinc concentrate to the Pueblo smelter regularly. J. C. Reagan is manager.

LAKE COUNTY.

The shaft on the Highland Mary property on Breece hill has cut 23 ft. of \$10 ore with some streaks of higher grade. The vein is almost flat, dipping about 15° to the southeast. Peter B. Horrigan is manager.—The ore recently cut by the shaft of the Iron-Silver Mining Co. at Leadville assays about \$40 per ton. The vein was cut at a depth of 1150 ft. on a lime-quartzite contact. William Carson is superintendent.—The Progressive mine has been equipped with new machinery and will be shipping ore in a short time. Al Ganz is manager.—The Valley mine on Little Ellen hill is shipping two cars of 40% lead ore per day.

LA PLATA COUNTY.

(Special Correspondence).—The May Day is shipping regularly.—The Lucky Four mine is being developed by a cross-cut near the level of the La Plata river, which is being driven with a Temple drill.—The Tomahawk Mining Co. is installing a 6-drill compressor and Heine water-tube boiler at its mines near the head of Basin gulch, and is contemplating the erection of a mill. T. J. Crowdis is superintendent.—R. H. Toll, backed by Denver capital, is re-opening the old Comstock mine. This mine was the first producer in the district, and in the middle '70s about \$75,000 was taken out of shallow surface workings, the ore being hauled by ox-teams to Pueblo, a distance of 300 miles.—The old Cumberland mine, near the head of the La Plata river, has been taken over by A. J. Clark and associates, of Telluride, and extensive improvements are being made. The 50-stamp mill is being remodeled and a large cyanide plant added. This property has been idle since before the cyanide process came into common use, and is said to have large bodies of \$28 ore blocked out which will yield 80% of its value to cyanide treatment.—It is reported that W. J. Adams, of Telluride, has leased the Columbus mine, a mile from the Cumberland. The property is said to have very good ore in the stopes.—At the head of Bedrock gulch two companies are resuming the development of the large low-grade copper deposits in the porphyry of that region.

La Plata, July 19.

OURAY COUNTY.

The machinery at the Calliope mine north of Ouray has been put in good running order and the buildings repaired. An ore-shoot from 15 to 18 in. wide has been cut by the 700-ft. adit, and a drift started. Tim Marlon is superintendent.—Fred Herzinger is shipping regularly from his lease on the Black Girl mine.—A cross-cut is being run from the Khedive level to tap the old workings of the Wedge mine. This will unwater a large portion of the mine so the pillars left from former operations can be drawn. F. M. Jackson and E. C. Weatherby have a lease on the property.—The Frank Hough mine on Engineer mountain is shipping 30% copper ore to the Durango smelter.

PARK COUNTY.

The Lincoln mine has started a force of teams hauling ore to Alta. There is considerable talk of building a smelter at that point to relieve the mine owners of the heavy freight to the smelter towns.

SUMMIT COUNTY.

Louis R. Johnson, who holds an option on the Iron Mask mine at Kokomo, is to install a compressor plant shortly. There is a good body of sulphide ore opened on the property.—An 8-ft. vein of carbonate ore has been opened on the Boston group at Mayflower by the Thompson brothers.

In the Atlantic mine on North Star mountain a 3-ft. vein of ore is being opened, samples from which assayed \$100 per ton.—The Lee-Gross mine is working on a vein that assays between \$16 and \$20 per ton.—The old Ling mine has been bonded and is being re-opened.—At the Arctic mine a 10-stamp mill has just been completed and is now

running on good ore. The company has also installed an electric drill in the mine. E. P. Jones, of Breckenridge, is manager.—At the O'Reilly group a cross-cut adit is being driven that will intersect the vein, giving several hundred feet of backs. The company expects to install an electric drill shortly. A. C. Howard is in charge of the property.—The tramway from the Silver Wave mine to the Montezuma mill will be completed before the end of the month. The mill is equipped to handle 250 tons of ore per day. E. B. Pfost is manager.—Frank P. Rosengarten has driven an adit 1000 ft. along the vein on his property on Collier mountain and opened a 300-ft. ore-shoot.—A vein has been cut at the Wellington mine on Mineral hill that assays 35% lead and \$20 gold per ton.

TELLER COUNTY.

Ganson, Halcrow & Taylor have secured a lease on block 25 of the El Paso Consolidated Gold Mining Co.'s property on Beacon hill.—A rich surface discovery has been made upon the Climax No. 1 claim on Squaw mountain, by lessees of the Little Puck Gold Mining Co., and the ore is being sacked for future shipment.—The Gold Dollar Consolidated Mining Co. paid a dividend of $\frac{1}{2}$ c. per share, a total of \$12,500.—A drift has been run 130 ft. on the vein recently opened on the 1300-ft. level of the Vindicator. On the 1400-ft. level a drift is being driven along the No. 2 north vein, which averages $2\frac{1}{2}$ ft. wide.—Hanson & Stewart, leasing from the El Paso Consolidated Gold Mining Co., have opened a 3-ft. vein on the 200-ft. level of the Little May mine that carries a high percentage of calaverite. The ore is being sacked for shipment.—Allen L. Burris has secured an option on the Doctor Jack Pot Mining Co., the Jack Pot Mining Co., and the Jennie Sample Consolidated Mining Co., representing a total acreage of 151.36 acres on Raven and Gold hills, for a New York syndicate.—A new vein has been cut in the Chicken Hawk mine on Guyot hill that contains both milling and smelting ore. Charles Walden is manager.

IDAHO.

BLAINE COUNTY.

Two veins have been opened on the surface of the Willow Creek property that mill about \$5 per ton. The 230-ft. adit is being driven to cut the main vein at a point that will give about 200 ft. backs. C. A. Stuart is president of the company.—P. A. Danahar has leased the Idaho-Democrat and installed a pumping and hoisting plant. The shaft will be sunk 400 ft. below the present workings and the vein explored from that point.

IDAHO COUNTY.

The sawmill machinery for the Elk City Dredging Co. is now being erected to supply the lumber to build the dredge on Elk creek. H. M. Williams is in charge of the work.—A contract has been let to drive the adit on the Gold Bullion property 120 ft. This should cut the ore-shoot opened by the old shaft. On the Columbia property of the same company a contract has been let to drive the adit 250 ft. G. M. Carter is in charge of the work.—On the Center Star property of Murphy, Brown & Tiedman, near Elk City, a 20-ft. vein has been opened that assays about \$25 per ton.

NEZ PERCE COUNTY.

Operations have been resumed at the Iron Spar mine near Lookout. A drift has been run 700 ft. along a vein that is over 40 ft. wide. John Curran is manager.

OWYHEE COUNTY.

The adit at the mill level of the Banner mine has cut several stringers of ore and it is expected to intersect the main vein shortly.—The Potosi mine at Silver City is to resume operations. J. E. Masters is superintendent.—The Bonnell mine in the Flint district is sacking rich silver ore for shipment.

SHOSHONE COUNTY.

The adit of the Tucker Mining Co. is in 400 ft. It is being driven to cut a vein of copper ore at a depth of 400 ft. that measures 50 ft. across the outcrop.—The drift on the property of the Silver State Mining Co. is opening a body of lead-silver ore. M. C. Lacey is superintendent.—The Pine brothers, of Wardner, have opened a 6-in. vein of

galena on their Pine creek claims.—Work on the Rhode Island has been suspended on account of poor ventilation. A blower will be placed at the mouth of the shaft and the work of cross-cutting from the 100-ft. level to the vein continued. Assays from the outcrop run \$8 gold and 7% copper. F. J. Martin is manager.—The Midway-Summit Mining Co. has purchased a compressor and rock-drills and is installing them on its property between Burke and Mullan. A good showing of galena has been made in the upper workings and the company is running a lower cross-cut to tap the orebody. George Herron is superintendent.—The Imperial Mining Co. near Burke is building an auxiliary electric-power plant that will connect with the Washington Water Power Co.'s line. The company is opening a vein of lead-silver ore.—The Orofino Mining Co. has placed a block of stock on the market to raise money for the construction of a mill at the Orofino mine east of Murray. The plant will have a capacity of 100 tons per day and will be completed this year. The company is shipping its high-grade ore and blocking out the lower-grade for the mill. P. Burke is manager.

MICHIGAN.

The excavation work has been completed for the new stamp-mill for the King Phillip and Winona companies and the foundations are being laid. The material for the superstructure is on the way.—The Adventure Consolidated Mining Co. is down 40 ft. with its vertical shaft, with which it will develop its three newly discovered veins. The first of the three veins will be reached at a depth somewhat greater than 900 feet.

MONTANA.

MISSOULA COUNTY.

Plans are under way for the erection of a concentrating plant at the property of the Tarbox Mining Co., near Saltese. The company has opened a large body of low-grade lead-silver ore. Richard Dixon is superintendent.—Kansas City capitalists have bonded the La Casse brothers' placer claims on Cedar creek for \$250,000 and are installing a dredge on the property. The gravel runs 5c. per cubic yard, and the claim covers a distance of three miles along the canyon, including several water-rights.—A new hoist has been installed at the Iron Mountain mine and operations resumed. A station has been cut on the 1700-ft. level and shipping will be resumed shortly.

NEVADA.

CHURCHILL COUNTY.

The clean-up at the Fairview mill for two weeks run amounted to \$4000. The mine has a large quantity of milling ore blocked out that will keep the mill busy for several years. Tom Gordon is superintendent.

ESMERALDA COUNTY.

(Special Correspondence).—A 2-ft. vein of gold-silver ore has been intersected 20 ft. below the 185-ft. level at the Grutt Balloon Hill.—The Lillian lease has cut a rich shoot of ore on the 100-ft. level.—The Queen Mining Co. has discontinued mining on company account, and the work will be carried on by lessees, who pay a royalty of 30%.—The Victor lease on Yankee Girl has opened a 4-ft. vein of ore assaying \$85 per ton. Frank McKelvy is superintendent.—The Miller lease on Coalition is sinking and cross-cutting from the 200-ft. level.—A station is being cut at the 400-ft. level of the Mint shaft, where a vein of high-grade sulphide ore has been opened.—The reduction plant of the National Ore Purchasing Co. is rapidly nearing completion, and the management expects to be in a position to receive ore about the end of July.

Rawhide, July 16.

LINCOLN COUNTY.

Plans are under way for the construction of a smelter for the Nevada-Utah Mines & Smelters corporation of Pioche. The plant will have an initial capacity of 500 tons per day and will treat custom ore. The company has curtailed the output of the Day mine to 50 tons per day. James P. Gas-kill is manager.—The Boston & Pioche Mining Co. shipped two cars of high-grade ore to the Salt Lake smelter.—The Oregon-Pioche has installed a gasoline hoist and will sink

to the 200-ft. level.—The east drift on the 300-ft. level of the Golden Prince cut a 20-ft. orebody that averages about \$15 per ton. Dean R. Low is in charge of the work.

NYE COUNTY.

(Special Correspondence).—The Montana-Tonopah has increased its extraction from 89½ to 92½%. The company is shipping between 100 and 150 tons of concentrate per month.—It is reported from Philadelphia that James S. Austin, president of the Tonopah Mining Co., is in favor of sinking the main shaft of the Tonopah to the 2500-ft. level, if necessary, to avoid the rock intrusion. It is likely that the extra dividend of the company will be abolished at the next meeting of the directors. The last 800 ft. of the 1500-ft. shaft is in a barren zone, and the management desires to pierce this intrusion as soon as possible.—The Belmont shaft continues in good ore.—The first shipment of ore, approximating 80 tons, from the Ellendale has been made to the sampler at Millers. The ore came from the North Star claim.—Lease No. 1 on Sunnyside Extension at Round Mountain is taking out rich ore. The incline shaft is down 80 ft.—The capacity of the Johnnie mill has been increased by the installation of Pierce amalgamators. During June the stamps treated 55 tons per 24 hours for 26 days. It is expected that the monthly clean-up will be considerably above that of former periods.—The Moore-Chindgren lease at Central, near Manhattan, has opened a deposit of some of the richest gravel yet found.—The Victor has cut a 6-in. streak of silver ore running \$200 per ton.—The main shaft at the Mogul is down 584 ft., with a 7-ft. vein opened at the 400-ft. level. On the 100-ft. level the north cross-cut has been extended 600 ft. The main vein is 6 ft. wide and assays from \$10 to \$15 per ton. The company is contemplating the erection of a 50-stamp mill in the near future. J. V. Priest is manager.—The orebody at the Golden Anchor has been opened for 300 ft. and is from 18 to 30 in. wide.

Tonopah, July 17.

The Solid Gold mill at Round Mountain has been started on company ore. The pipe-line from the Shoshone mine has been completed and the mill is assured of a plentiful supply of water. C. Johnson is manager.

STOREY COUNTY.

A vein of high-grade galena ore has been cut on the property of the Cooney brothers in the Badger district, 14 miles northeast of Virginia City. The vein is 1½ ft. wide and assays about 500 oz. silver per ton and 20% lead.

WHITE PINE COUNTY.

The shaft of the Boston-Ely is to be stopped at the 850-ft. level and a heavier hoist installed. On the Matilda claim a streak of ore assaying 15% copper and \$70 gold is being followed. Ed. W. Ralph is superintendent.—The strike situation at Ely remains unchanged. The shooting of two Austrian miners by deputies has caused an extremely bitter feeling toward the mine owners. Thomas Corra, the Denver representative of the Western Federation, is at the scene of the strike and every endeavor is being made to prevent further bloodshed. The strike is due to a cut of 50c. per day in the miners' wages.

OREGON.

BAKER COUNTY.

Several tons of high-grade ore were shipped from the vein recently cut in the Buffalo Monitor mine for a trial run. Drifts have been run on the vein in both directions and some good ore opened. C. L. Cox is manager.

GRANT COUNTY.

Walter G. Gleason has purchased the Independence group of quartz claims near Granite for \$6000.—The Amazon Mining Co. has acquired four additional claims in the Greenhorn district.

JOSEPHINE COUNTY.

At the Waldo copper mine 3000 tons of ore are stored on the dump. In the mine the work is confined to blocking out the ore in anticipation of the starting of the Takilma smelter which, with the Queen of Bronze mine, is at present closed by litigation.

NEW MEXICO.

OTERO COUNTY.

Lack of material has held back the work on the smelting plant of the Orogrande smelting plant at Orogrande, but it is expected that the furnace will be blown in the latter part of this month and the mines started.—L. D. Baker, of Oklahoma, has purchased the Mamie group of claims in the Orogrande camp from Joseph P. Mocker for \$25,000.—A good tonnage of ore is piled on the dump of the Delusion mine, and three cars of ore were recently shipped to the El Paso smelter. Charles H. Knibbs is in charge of the work.—Culver & Downs have sunk a 200-ft. shaft on the Gem group that cut a 15-ft. vein of sulphide.—The raise from the 200-ft. to the 90-ft. level on the Monarch property opened a good shoot of ore. George E. Moffett is in charge of the work.

TEXAS.

LLANO COUNTY.

(Special Correspondence).—The work of proving the extent of the iron-ore fields in the vicinity of Llano has been going on for several months under the direction of William B. Phillips, who represents Robert Downman, of New Orleans, and associates, who own the Iron Mountain mine and other deposits of iron ore in that section. The Texas railroad of J. J. Hill and associates is being extended toward Llano, and preparations are being made to extend the Fort Worth & Rio Grande division of the Frisco system south from Brady. These roads will place the Llano iron-ore field in direct touch with the coalfields of Thurber, 100 miles distant.

Llano, July 20.

TRAVIS COUNTY.

(Special Correspondence).—It is the present intention of Governor Campbell to convene the Legislature in special session in November or December of this year. If he does so, he will be urged to submit a recommendation to that body for the enactment of an adequate mining law. The Legislature at its session a few months ago passed a new mining law which embodied in its provisions features that met with the approval of men interested in the mining industry who desired to see the mineral resources of the State developed. This bill was vetoed by the Governor because of an alleged unconstitutional provision relating to the submerged lands along the Texas coast. The vitiating provision had no place in the bill, as it was foreign to the subject for which the Act was intended to relate. It was near the closing session when the bill was vetoed and opportunity was not afforded for the re-introduction of the measure. The State owns a vast acreage of land in the mineral region of Texas, and with the encouragement and protection of an adequate mining law prospectors would be quick to avail themselves of the opportunity of exploiting these lands. The existing mining law of Texas is really a prohibitive measure, so far as inducing mineral development upon State lands is concerned. It imposes a heavy burden upon the prospector from the very beginning of the location of the claim, and should paying mineral be found, the State Land Commissioner is authorized to fix any price for the property that he may see fit. No prospecting has been done upon State lands since the law was passed.

Austin, July 19.

UTAH.

BEAVER COUNTY.

The Cactus mine at Newhouse has resumed operations and the mill started. The company hopes to produce copper at less than 9c. per pound. Samuel Newhouse is manager.—The shaft of the Cupric Mines Co. cut some excellent copper ore at the 325-ft. level. The ore occurs in large kidneys, and several shipments have been made to the Tintic smelter. M. C. Morris is manager.

JUAB COUNTY.

The Montana Mining Co. has made its first payment of \$10,000 on the Mellich group of claims in East Tintic.—On account of a break in the machinery the Opex mine at Mammoth has been shut down a week. A slight flow of water was struck on the 2180-ft. level. A new station pump

will be installed at that level and sinking continued. Frank P. Swindler is manager.

SALT LAKE COUNTY.

The Tintic Mining & Development Co. has accepted several contracts to smelt custom ore at its Yampa smelter.—A new compressor and hoist has been installed at the property of the North Utah Mining Co. in Markham canyon, and other equipment is to be added shortly. W. D. Bohn is manager.—At a stockholders meeting the directors of the Emma Copper Co. proposed the issuing of 150,000 shares of stock to raise money to cover the present indebtedness and carry on development work.—A new company, known as the Yosemite Mining Co., has been organized to work the Yosemite and Cluster mines, near Bingham Canyon. It is understood that the Bingham Mines Co. is interested in the new organization.

SUMMIT COUNTY.

The Western Monitor Mining Co., operating in the head of Iron canyon, is sinking a double-compartment shaft and running several drifts in a body of iron ore.—The New York Bonanza is to be unwatered and sinking resumed at the 800-ft. level. A station will be cut at the 1000-ft. point and cross-cuts run from there to explore the orebody that has been opened in the upper levels. M. J. McGill is manager.

UTAH COUNTY.

The adit on the Mineral Flat property at American Fork cut 3 in. of ore. The contact was cut 200 ft. above, showing 4 ft. of vein matter, and an adit has been started 500 ft. below. The Mineral Flat mine is one of the Knight properties.

WASHINGTON.

FERRY COUNTY.

Two drills have been installed on the property of the South Republic Mining Co. at Republic and two more will be added to the equipment in a short time. Drifts on the 250-ft. level have opened some good ore. M. Hollis, of Spokane, is manager.—A dividend of 1c. per share will be declared August 1 by the New Republic Mining Company.

OKANOGAN COUNTY.

Extensive plans have been completed for the financing and development of the Q. S. Mining Co.'s property. The outline includes the building of 75 miles of electric road from Nighthawk to Brewster and a smelter near the mine. Adelbert M. Dewey, of Spokane, is manager.

STEVENS COUNTY.

The Ark Group Mining Co. has opened a good body of silver ore three miles south of Kettle Falls. J. J. Burke is manager.—The Crystal mine near the mouth of the Spokane river has been sold by John Gray, representing the Crystal Mining Co., to French capitalists.

CANADA.

BRITISH COLUMBIA.

At Miskatiah bay, 20 miles from Kitimaat, a rich outcrop of copper ore has been opened about 500 ft. above the sea-level. The ore is copper glance assaying about 60% copper and 48 oz. silver per ton. The ore was discovered by James McLennan.—The main drift of the Fife Mines, Ltd., property at Fife has been driven 400 ft. along the vein and a raise made to the surface. Much of this work has been through ore that runs from 3 to 6% copper and from \$4 to \$8 gold. A winze has been started in ore and the output of this is being shipped to the Trail smelter.—A dividend of 2s. per share has been declared by the Le Roi No. 2 company.

ONTARIO.

The Townsite Mining Co. has disposed of a large block to English operators and has resumed operations.—A new vein of cobalt ore carrying a high percentage of silver has been opened on the Nova Scotia property.—At the Strathcona four diamond-drill holes are being run to cross-cut the vein system of the property. The first hole is down 350 ft. and has cut several small veins that show traces of cobalt and silver. A compressor, two boilers, and a rock-drill have been added to the equipment of the property.

QUEBEC.

The Golconda Gold Mining Co. has nearly completed the buildings at its property near Sherbrooke and will install the machinery in a short time.—William Marshall is financing the Compton Gold Dredging Co., which is the first operator to work dredging ground in the Province.—The Black Lake Consolidated Asbestos Co. has been organized at Montreal to consolidate the Union Asbestos,

Map Showing Portion of Quebec.

Southwick, Black Lake Chrome & Asbestos, and Imperial Asbestos companies.

MEXICO.

CHIHUAHUA.

A force of men has been put to work in the Prieta mine near Parral blocking out the ore in anticipation of the 30-stamp mill that is to be erected on the property. D. H. Bradley, Jr., is in charge of the work.—A new set of boilers has been installed at the power plant of the El Rayo Mining Co. George H. Schroter is manager.—The silver mines of the Candalaria Mining Co. at San Pedro have been unwatered and are shipping regularly to the El Paso smelter. The July output will approximate 200 carloads.

GUADALAJARA.

As the result of a favorable report upon the Cinco mine in the Hostotipaquillo district by John B. Farish, the company will erect a 5-stamp experimental mill, and later a 250-ton reduction plant, when the correct treatment for the ore has been outlined. The mine was purchased last year by the Marcus Daly estate for \$530,000.—The Makeever adit at the El Favor mine cut a 55-ft. vein at a depth of 750 ft., the greater part of which is ore of milling grade. The work on the reduction plant is proceeding rapidly. A. A. Watson is in charge of the work.

Special Correspondence.

NEW YORK.

Goldfield Consolidated Quotations.—Other Nevada Stocks.—Curb Regulations.—San Toy.—Planet Copper Mine Sold.—Big Vein Copper.—Alvarado Consolidated, Mexico.

For several weeks Goldfield Consolidated stock has been erratic on the New York Curb, and it still has a declining tendency. The decline in this stock, together with ugly rumors in circulation to explain it, coming after the recent slump in Goldfield Daisy, has had a bad effect on mining investments generally. The investing public has lost heavily in both these mines and in the Rawhide Coalition, and Nevada mining investments will for some time feel the bad effects. Many investors appear puzzled as to the cause of the slump in Goldfield Consolidated stock. The explanation, however, seems simple. It is the result of loss of confidence in the management of the company following the exposure of its market rigging and the recent stock deals with Hayden, Stone & Co., Scheftels & Co., Barney & Co., Baruch & Co., and other Jewish houses. The mine is controlled by George Wingfield, erstwhile Tonopah saloon-keeper, and a mining promoter. Two years ago he added several fresh mining leases to the company's holdings and the company was re-organized with a capital of \$50,000,000. This capital was criticised at the time of the re-organization as excessive; but by ingenious manipulation, and by saving the rich ore in the mine for the first crushing at the new mill to make a fine showing, the stock was run up to \$7.50 per share. The public took a large amount of it at about that price. Large blocks of the stock were also placed in Europe by the Jewish houses who loaned Wingfield the money to buy the Combination mine, receiving large stock-bonuses. Even at the present price the stock is considered unsafe, and the public shrinks from putting further money into any of the disgraced corporations, the Goldfield Consolidated, the Daisy, and the Rawhide Coalition. It is regretted by local mining men that the rank manipulation in the above companies' stocks was permitted to continue so long without exposure.

The agent of the New York Curb market, as the result of the numerous exposures of scandals relative to mining corporations, has issued to the secretaries of all mining corporations whose stock is traded in a form of statement to be filled monthly. The Curb committee desires to know something about the corporations whose stock they handle daily, and they want to be in a position to answer some of the inquiries frequently put by the investing public. The agent requires mining companies desiring Curb privileges to regularly forward to the agent monthly statements. On the asset side such statements must show the amount of cash it has on hand and in bank, accounts receivable, ore and bullion with smelters and bullion dealers, concentrate ready for shipment, bullion in vault ready for shipment, ore on dump and ore broken in mine, stores and supplies, plant tools and equipment, and mining rights. On the liability side must be disclosed: unpaid interest, unpaid dividends, notes and accounts payable, trade creditors and miscellaneous, officers of the company, employees for wages; reserve for transportation and treatment; surplus, capital and surplus, capital, common, par value preferred in treasury dividends, rate, when and where payable; date of last dividend paid; bonds (state first mortgage or otherwise), bonds outstanding, bonds in treasury, denomination (if coupon registered), when dated, when due, interest, when and where payable. This is a commendable move and may result in good. It is doubtful, however, whether many of the companies traded on the Curb will dare to furnish the required information. If the public were in possession of it, stock prices would rapidly change and manipulation would be ineffective.

The directors of the Alvarado Consolidated Mines, Mexico, report that the public has subscribed to the treasury stock recently offered with the view to erecting a cyanide plant. The treasury now holds \$1,000,000 cash, which will be im-

mediately expended in a cyanide plant, and in other necessary machinery. Boston interests are active in advancing the price of San Toy stock in New York, Boston, and Pittsburgh. The San Toy is one of Thomas Lawson's Mexican promotions, and is capitalized at \$6,000,000. The par value of the stock is \$1. Lawson is also handling the Chino company's stock. This is another Mexican company he lately promoted.

The General Development Co., of New York, a Lewisohn concern, has purchased the Planet Copper Mining Co.'s property, Yuma county, Arizona, on the recommendation of W. H. Weed, its copper expert. The Planet company is a New York concern, which was organized under the laws of Arizona in 1902. The Planet mine is an old one and has produced some rich ore. The company's holdings comprise 25 claims, having an area of 500 acres. Three incline shafts have been sunk on the vein. The deepest incline is down 800 ft. The vein is of large size and is capped with iron. The shipping ore averages about 8% copper. A large price was given for the mine. The Big Vein Copper Co., of Tucson, Arizona, is the latest copper company to have its stock listed on the New York Curb. This company was recently organized under the Arizona laws with a capital of \$10,000,000. The company expects to develop a copper prospect. Lee Shubert, the theatrical man, is one of the directors. The New York stock market has been dull and heavy lately. Steel common has been highly manipulated, and it is generally believed that it will be run up to 75 as soon as J. Pierpont Morgan returns to New York. Mr. Morgan is returning to take part in the flotation of the Panama loan. While he is in the City the stock prices will not be allowed to decline materially.

LONDON.

East Pool and Carnbrea, Cornwall.—Wanderer Mine, Rhodesia.—British Eight-Hour Law.

It is regrettable to record the falling off in tin-content at the East Pool mine in Cornwall, and the consequent financial embarrassment of the company operating it. For a great many years the mine yielded large profits, and it successfully weathered the periods of depression in the tin market. Four years ago the directors commenced to re-organize the dressing plant. Before dismantling the old Cornish stamps, two heads of air-cushion high-speed stamps were erected on trial. In addition Frue vanners and Wilfleys were provided, and a Wetherill magnetic separator was erected for the purpose of separating the tin from the wolfram. The ore is highly complex, and contains, besides tin, a fair amount of wolfram, arsenical and copper pyrite. Successful metallurgical treatment requires constant experiment, and a considerable number of processes are involved. A year ago it was decided to provide four more heads of air-cushion stamps, and to do away with the old Cornish stamps entirely. Thus the whole plant is renovated, and is now ready for operations. For more than six months it has been known that the lodes have become poorer, and at present heavy losses have been made in the working, and shareholders are having to pay up. It should be mentioned that East Pool is one of the few remaining mines using the cost-book system, but unlike most others it has not been in the habit of dividing profits up to the hilt, as may be seen from the fact that the new plant has been provided entirely out of income. It is probable that the company will now have to adopt limited liability, for it is evident that larger sums will be required for underground development than the present shareholders will care to put up. Scientific exploration on a systematic scale will be requisite, if the ore supplies are to be maintained. The mine recently lost its manager by the resignation of Captain Tamblin, and Captain Jennings has succeeded him. Captain Tamblin was one of the old school who believed in the ancient dictum, "where it is, there it is." It is no disparagement to him to say that East Pool, under the direction of a more scientific student of ore deposits, may again become profitable.

In writing of the Carnbrea mine, adjoining East Pool, some months ago, I mentioned that at this mine much of

the tailing was stacked instead of being discharged into the Red river, as is the usual custom in the Camborne district. Also there are large dumps of low-grade ore which have never been treated. There is now some prospect of these dumps and residues being worked. In some cases they have paid and in others losses have been incurred. The project at Carnbrea has been put before the directors by outsiders who will take the risk themselves and pay the company a royalty on the ore treated. As the surface at the disposal of the company is limited, the dumps will be transferred for treatment at the old Wheal Agar property, where ball-mills and concentrators will be erected. It is estimated that the dumps average 8 to 9 lb. of black tin per ton.

It would be difficult to find a lower grade mine worked at a miner's profit than the Wanderer, in Selukwe, Rhodesia. The extraction at this mine is only a fraction above 2 dwt. per ton, and yet the mining expenses are met. During the twelve months ended April 30 last, the mill treated 186,708 tons of ore, and recovered 18,906 fine ounces, which is an average of 2.024 dwt. per ton. The amount realized by the sale of the gold was £80,392, and the mining costs were £64,535. A profit of £15,857 is thus shown, but after other expenses in Rhodesia and London have been paid there is not much left. In fact the necessary allowances for depreciation have put the balance on the other side. For instance, consulting engineers' fees run to £2700, directors' fees £800, and so on. The amount written off for depreciation is £17,149, which seems large, but it must be remembered that the property-account in the balance-sheet stands at a high figure. The ore at this mine is a gold-bearing sandstone, and the extraction is effected by dry crushing and cyaniding. The gold-bearing bands are narrow, and mining there involves the removal of barren overburden. The ore reserves at present consist of practically two years' supply. The company is about to take over the Camperdown mine, belonging to the Matabele Proprietary Mines Co., which it has been working on lease for some time. The ore here is of higher grade, averaging 4.65 dwt., and the supply already exposed amounts to 325,000 tons. The directors of the company have taken the opportunity presented by the purchase of this second mine, to re-organize, and to write down the capital to a more suitable figure. In this way future profits will be made available for the distribution of dividends instead of having to be applied to the writing off of expenditures charged to capital in earlier years. Accordingly a new company will be formed with a capital of £150,000 in 600,000 shares of 5s. each, instead of the present capital of £450,000. Of the new shares, 431,386 will go to shareholders in the present company, 134,007 to the Matabele Proprietary for the purchase of the Camperdown mine, and 34,607 will be held in reserve for future issue.

On July 1 the new Act relating to the time spent by miners below ground in coal mines came into force, and in spite of many prophesies to the contrary, the coal trade appears to be none the worse. The preliminary struggle for an 8-hour day reckoned from bank to bank, both in and out of Parliament, was a keen and bitter one. Originally it was demanded by the coal miners, who it must be remembered form no small portion of the working class of England, that they should by law be prevented from being underground more than 8 hours out of the 24. The masters objected to this demand, and pointed out that descent and ascent and the traveling along the levels and back occupied a substantial amount of time, which would reduce the actual operating time to 7 hours in many cases. Eventually a compromise was effected, and the law as it stands reads as follows: "A workman shall not be below ground in a mine for the purposes of his work or of going to and from his work for more than 8 hours during any consecutive 24 hours; no contravention of the foregoing shall be deemed to take place in the case of a workman working in a shift if the period between the times at which the last workman in the shift leaves the surface and the first workman in the shift returns to the surface does not exceed 8 hours." It will thus be seen that on an average only half the time occupied in going to and from the face

will be reckoned in the 8 hours. Another provision in the Act is that during 60 days in the year the colliery proprietors may demand 9 hours work instead of 8 hours. There is also another section which empowers the King in council to suspend the Act altogether in event of war or national danger, or of grave economic disturbance due to the demand exceeding the supply. The colliery owners would like, as a sort of counterblast to the 8-hour work in any consecutive 24, an enactment requiring the men to come to work when wanted. The colliers are independent men and take wholesale holidays when so disposed, and the employers would like them to be subject to a minimum per week as well as a maximum per day.

DAWSON, YUKON TERRITORY.

Dredge Record.—Yukon Ditch.—Electric & Hydraulic Elevators.—Miller Creek Concession.—Quartz Mines.—Prospecting.

Summer work is now well under way, and conditions point to an increase in this year's gold production. The total output this year may be nearly \$3,750,000. The water supply has been better than usual, and this is sure to have a good effect on the output. All of the dredges, 10 in number, are doing excellent work, and the result of hydraulic mining for the season, has been, on the whole, satisfactory.

The big ditch of the Yukon Gold Co. is behaving splendidly, delivering at the present time 4000 miner's inches of water at the Klondike, where part of it is being turned into

Map of Alaska.

the river on account of lack of equipment. This is unfortunate, but owing to transportation difficulties it was impossible to land the required pipe in time to get the earliest use of this water. The fact that the ditch will deliver such a large body of water the first year is gratifying. There have of course been breaks, and ditch-troubles of various kinds, but so far they have not been serious. The several inverted siphons have all stood the test of a full head, and are giving little trouble and no anxiety. The new unit which was added to the power-plant this spring is working well, so that there is plenty of power on hand for all needs. The company has at present seven dredges at work, and so far as can be found they are all doing good work. The electric elevators, of which two are working on Bonanza creek, are handling lots of rich dirt. Both of these elevators are soon to be moved ahead and started in a new cut. This will possibly take some time, but it is understood that the engineers in charge have arranged for every contingency. No unnecessary time will be lost. An Evans hydraulic elevator is now being installed on some of this company's property on Bear creek. It is almost ready for work, and will use water from the main ditch, with the big head that will be available, and also a large volume of water.

The Canadian Klondike Co.'s dredge on the Boyle Concession at the mouth of Bear creek is doing well. This boat has always been a success. It is working under unusual advantages for this country, for the ground is not frozen, and it will be several seasons before they are compelled to thaw, if indeed this ever becomes necessary.

The Lewis river dredge on Bonanza creek, of which Edward Simpson is resident manager, is also having its usual success. It is expected that this will be the last year for this dredge at the point where she is now working. With good luck this ground will be all dredged out this fall. The understanding is that they will remove the boat to other property which they own this winter. The dredge has done noble service in the past. The Bonanza Basin Gold Dredging Co.'s dredge is trying hard to beat the excellent record made last year. They are moving lots of dirt, and the value of the ground is believed to be satisfactory. This boat has good management. J. A. White, an old-time Oroville dredge-master, is in charge of the boat, and James Wortham is resident manager. The dredge working on Stewart river is generally understood to be progressing satisfactorily. Gratifying results are being obtained by the Walkers Fork Gold Dredging Co. The difficulties of last year have all been overcome, though the boat is not yet working up to her supposed capacity. The disappointment in the boat is, however, overshadowed by the output, which has been quite up to the mark this season.

On the whole, dredging in this region, in the face of the frozen condition of the gravel, must be called a success, and from year to year, as conditions become better understood, its success is being made surer. Intending investors should bear in mind the necessity of securing up-to-date dredges. They should not allow themselves to be influenced by small outside concerns that will build 'just as good' a dredge for less money than the well established types.

In the Sixty-Mile country, on the N. A. T. & T. Co.'s property, better known as the Miller Creek Hydraulic Concession, considerable work is being done. This company expects to install a dredge as soon as the ground can be prepared for successful working. The work at present consists of stripping the gravels of the overburden of glacier muck by hydraulicking, and thereby exposing the underlying gravel to the heat of the summer sun, which quickly thaws the gravel, thus avoiding the necessity of artificial thawing. Gratifying results are being obtained in this way. On Glacier creek there is a good deal of mining in progress in a small way. Some operators have been particularly fortunate during the past winter and have fat pokes to show for their strenuous life. Among the most successful are Pete Allen and Edgar Searle. This is the most prosperous outlying district in the Yukon Territory. It is 65 miles west of Dawson and $3\frac{1}{2}$ miles east of the Alaskan boundary line, and is reached by a wagon-road from Dawson.

Work is progressing well on the two quartz properties now being developed in this district. The tunnel that is being driven to cross-cut the five parallel veins owned by Hartman and Davidson on Lombard creek is now in 550 ft., and it is expected that the first vein will be cut within the next 150 ft. At the present time 9 ft. per day is being made. The tunnel is $4\frac{1}{2}$ by 6 ft. The equipment consists of two No. 5 Model C and three No. 3 Model C Leyner drills, a six-drill compressor, and a 60-hp. boiler; also a complete electric plant which furnishes light throughout the tunnel. A great deal of interest is centered in the success of this enterprise. On the Lone Star group, controlled by Dr. Catto, of Dawson, work is going steadily forward in a conservative manner. A 2-stamp Hendy prospecting mill has lately arrived in Dawson. This will be installed as soon as possible, as there is considerable good ore on the various dumps.

If as good prospects as are being found on the divides between Bonanza, Hunker, Sulphur, Quartz, and Dominion creeks were found anywhere in Nevada, for instance, there would be a camp of considerable size there within a month, but up here it is hard to change conditions. The placers must be worked out before the great development of the quartz veins can occur. This day is not far distant. Gold ore of good assay value is constantly being brought into Dawson from the surrounding country. There is no reason why permanent veins should not be found along the foothills of the 'Rockies', which lie 20 miles to the north and 50 miles to the east of Dawson. Rich 'float' is constantly being found along these hills. What is needed is efficient prospectors.

SALT LAKE, UTAH.

Smelter for Pioche.—Boston Con. and Utah Copper Merger.—Ohio Copper Mill.—Bingham Properties Consolidate.

A number of unavailing efforts have been made to provide a smelter for the Pioche mines. The question of a custom plant being constructed by the Utah-Nevada Co. is not taken seriously here. It is believed that Samuel Newhouse will be able to get the officials of the Ohio-Kentucky and Nevada-Utah together on a consolidation of interests in that district. Recently some officials of the Prince Consolidated held a conference with William A. Clark in New York, and it was agreed that the spur-line should be built from the terminal at Pioche to the Prince properties. It will be about ten miles in length, the mining company to do the grading and lay the ties, and the railroad company will lay the rails as soon as this work has been completed. The Prince company will get a refund for building the railroad in the form of rebates on its ore shipments. The question of a smelter was taken up at this conference, and Mr. Clark took a lively interest in it. He is now in the West and will go over the Nevada mining camps with a view to deciding upon the location of a custom smelting plant. Bullionville has been mentioned as a probable site for the furnaces. It is understood that Mr. Clark favors Las Vegas, as it will be nearer the centre of a site from which ores can be treated from Goldfield, Tonopah, Pioche, Searchlight, and other points touched by his railroad line. He expressed a desire to build the smelter on his own account, and had no hesitancy in saying that he believed sufficient ore could be obtained to keep a large smelter employed for a number of years. He has had his engineers in these camps for several months past, and he will check up their reports on the ore obtainable on this trip. He has instructed the Pioche shippers not to make contracts on their ore for more than one year from date.

Upon the return of Samuel Newhouse to this city, from his Eastern trip, he could not be induced to give out a statement regarding the consolidation of Boston Consolidated and Utah Copper. He said this would be a matter to be decided by the executive committee of the Boston Consolidated, and after they had reached a conclusion on this point, the directors might decide to submit it to the shareholders. Locally it is believed that the time is not ripe for a merger of these companies. David C. Jackling, general manager and vice-president of the Utah Copper, still insists that the directors of his company have not been considering any proposition for a consolidation of mines at Bingham; that it may be a matter that will be taken up later, when the Utah Copper steam-shovel operations have worked up close to the Boston Consolidated end-lines. At this time he can see no advantage to his company from joining interests with the Boston Consolidated. The general impression among mining men is that the Boston company is willing, but it is conceded that the Utah Copper can best afford to go on alone under existing conditions. When Colin McIntosh, general manager of the Ohio Copper, returned from his visit to the Eastern offices of the company, he was annoyed at the delay in the arrival of material for the steel trestle, which forms the connecting link between the mill and the Mascotte tunnel. He said they could not hope to have this work completed for several months. He has ordered the material for the second unit of the mill, which will be placed in position as fast as it arrives. The first section has been completed, and within 90 days they expect to have half the mill ready, and two sections will be commissioned at the same time. Development work on the third, fifth, and seventh levels in the mine is being continued, and the raise on the vein from the tunnel-level will complete connections in time to have the ore dropped down into the ore-trains by the time the mill construction is finished. Mr. McIntosh says that they succeeded in raising all the money they will need to complete the work now in hand.

An agreement has been reached by which the Bingham Metals and the Bingham Central Standard companies are to be merged. The holding company is to be known as the Utah Metals Mining Co. Transfer offices will be maintained

in this city and in Boston. Bingham Metals will get share for share in the transfer of stock for the new shares, and the Bingham Central Standard will be transferred at the rate of three shares of old for one of new stock. The two companies will own a combined estate of more than 4000 acres of patented ground. It extends from Carr Fork canyon over the range into Middle canyon, and will be within three miles of the International smelting plant. A mill will be built, and the Bingham Metals tunnel, now penetrating the mountain 3000 ft., will be continued to the Central Standard ore zone, which it will cut at a depth of 2300 ft. This tunnel can be utilized by other Bingham mines that may want to get greater depth, or to transport ores to the International furnaces. It is double tracked, is 9 by 9 ft., and has a drain of several feet under the track. It is carrying off 900 gal. of water per minute, and this water is utilized for power to operate the ore-cars, run the saw-mill, and provide light and power for the mines. This flow will be increased to 10,000 gal. when the mountain is opened on both sides. Ores will be shipped from the Central Standard mine through this tunnel to the smelter at a cost not in excess of 6c. per ton.

GOLDFIELD, NEVADA.

Hampton Stope.—Florence-Goldfield Mill.

At the present time a large production is being made from the Hampton stope and other parts of the Combination mine, as well as from the stopes opened from the southern extension of the Red Top workings and on the Lucky Boy claim. On the Laguna, extensive work has been started from the Hazel shaft at a depth of 720 ft. by the Chicago Cleveland Co., under the management of William MacKay. Ore of high grade was found near this shaft at 718-ft. depth, and the Consolidated is driving toward this ground from the Clermont shaft at the 600-ft. level. The Moore lease shaft on the Combination No. 2 is down 573 ft., where a station has been cut and drifts started.

At the Florence Goldfield mill everything is in readiness for the installation of the additional machinery upon its arrival, and it is announced that either a belt-conveyor or an aerial trolley will be installed to carry ore from the Little Florence shaft to the mill-bins. This conveyor will be operated by gravity, carrying the ore to the elevated bins. The main shaft at the mill is now being enlarged to a depth of 530 ft., and this work will probably occupy another six weeks. The shaft will be equipped with automatic skips, interchangeable with cages. At a depth of 450 ft. the Victor shaft of the C. O. D. Consolidated has penetrated the ore-shoot which has been productive at the upper levels, and production from the 200, 300, and 450-ft. levels will be resumed shortly. The ore carries a high percentage of gray copper and is of shipping grade. East of and adjoining the Blue Bull, operations on an extensive scale have been resumed by the Goldfield Imperial Co., and the shaft will be sunk to depth. At the 100-ft. level three strong veins are exposed containing ore of low grade. Three miles to the east the Pittsburg Nevada is developing a vein at 300-ft. depth. Several other mines in this neighborhood have resumed work recently, and on the Red Mountain belt the Nancy Donaldson shaft is down over 100 ft. and has exposed some ore of good quality. Shall shipments of high-grade ore have been made lately from lessees operating on the Velvet and St. Ives claims of the Goldfield Merger Mines Company.

MEXICO.

La Blanca, Pachuca.—Floods.—Labor Shortage.—Cananea Consolidated.—Mexican Mining Institute.

We understand that John Hays Hammond has confirmed the report regarding an option for purchase of La Blanca mine, Pachuca, mentioned last week, and that the intending purchasers are the English capitalists who control the Camp Bird mine in Colorado. The engineers are making an examination of La Blanca, and as it is the general belief that the property will stand the most rigid examination, it is probably simply a question of terms. The entry of

these people into Pachuca must mean much for the future of that city.

For several months during the early part of the year almost the entire Republic, by reason of the lack of spring rains, suffered from shortage of water and a curtailment of operations. Finally the rains and the floods came, during the last days of June and early July, with many wash-outs of wagon-roads and railroads, the losses reaching perhaps into the millions, and transportation was at a standstill. In addition to these troubles were those with the laborers, many of whom, when the rains came, left their usual occupation to sow and cultivate the little ranches in which they or their families are interested, with the result that many mines, mills, and other enterprises have had to curtail operations, and even shut down altogether. The Mexican peon is a difficult subject to hold steadily to his work. His observation of the national and church holidays is notorious, and these are so numerous that it is difficult for a large concern, particularly a smelter, which must keep running, to figure how they may pass certain holidays. Even this, however, is not as difficult a matter as it formerly was, the foreign influence apparently having reduced enthusiasm for the less important days. The question of holidays has been overcome by many companies, especially at the smelters, by a premium system or a bonus to the men who work more than a certain number of days of each month. This method has now been adopted by the Cananea Consolidated Copper Co., with excellent results; each man who works a minimum of 26 days during the month receives, as a premium in addition to his regular wage, 50 cv. for each day that he has been at work. This keeps the force together, an important factor where 3000 men are employed, as is the case with the Cananea company. The four days that the men may be absent without losing the premium are so scattered through the month, and among the different men, not all taking the same days, that there is no disturbance or inconvenience. The Cananea Consolidated Copper Co. is now treating close to 3000 tons of ore per day, most of which goes to the concentrating mill, though some goes direct to the smelter. From the resulting matte blister copper is made, amounting to 4,000,000 lb. per month, and containing 50 oz. silver and 0.3 oz. gold per ton. Additions, changes, and improvements are being continually made at both mines and smelter to keep down expenses and make a good showing under the present prices of copper. The ore contains only 2.4% copper, 1½ oz. silver, and 0.01 oz. gold, or about \$7.20 per ton.

Another of the large low-grade propositions in Sonora, that needs like careful attention, is the Moctezuma Copper Co., at Nacozari, which is handling 2000 tons of copper ore daily in its concentrating mill, and is now contemplating doubling the plant. The concentrate goes to the Copper Queen smelter at Douglas, Arizona, as both are controlled by Phelps, Dodge & Co. A short distance north of Nacozari, at Arizpe, the Clancy Bros. have taken over the Santa Rosalia mine, one of the important old producers, and are equipping it with modern machinery for the economical development and working of the property; and at the Belén mines, near Arizpe, a good grade of bismuth ore, running well in silver and gold, is being opened. The Chiapas Mining Co. has completed its 8-mile tram and has resumed shipments. On the old San Agustino a little work is being done. The Bocoachic placers, on which work has been carried on in a small way since 1904, have been taken over by an American company, and it is believed that they will now be worked properly and on a large scale. The Yaqui River Smelting & Refining Co. is preparing to resume operations as soon as the railroad reaches Toledo (now 25 miles from the terminus), when coke and other supplies may be brought in at a price that will admit of economical mining and smelting.

The Mexican Institute of Mining & Metallurgy met in its initial session on Monday, July 12, 1909, in Mexico City for the approval of the constitution and by-laws and the election of officers. There were present some 75 members, and the following officers were elected: president, A. Grothe; vice-presidents: Bernard MacDonald, Fernando Gonzales, and H. S. Denny; the Council: Kirby Thomas,

E. P. Merrill, Leopoldo Salazar, P. A. Babb, R. E. Chism, Victor M. Braschi, E. Ordoñez, J. J. Reynoso, Robert Hay Anderson, E. Girault, Ferdinand Susteric, and Ignacio Ibarguengoitia. The papers read were: 'The Aims and Objects of the Institute', by H. S. Denny; 'Smelting in High Altitudes', by R. L. Lloyd; 'Notes on Cyanide', by A. Grothe; 'Cyaniding Slimes', by Ferdinand McCann. The committee on membership reported a total roll of 115, with many applications not yet acted upon.

BUTTE, MONTANA.

Amalgamated.—Policy of Expansion.—Conditions at Ely, Nevada.
—Butte & Superior.—Greenwater.

Convincing manifestations of an era of industrial expansion for the Amalgamated Copper Co. are beginning to appear, and predictions are rife that John D. Ryan and William G. Rockefeller, successors to Henry H. Rogers in formulating the policy of the great copper company, will soon usher it in. Mr. Rogers was conservative in respect to increasing the properties of the Amalgamated, while Mr. Ryan has always entertained the view that the holdings of the company might be expanded with profit to the concern and to the public. It is rumored that it may not be long till the East Butte company's mineral territory and other property will be ranked among the holdings of the Amalgamated, and to that may be added the Davis-Daly and others in the Butte district. The story that the Davis-Daly concern may be taken over by the big copper company has emanated from interests in the former corporation, yet the policy of expansion for the Amalgamated is firmly expected by many people to materialize surely and quickly. It is pointed out that the prospective absorption of the Butte & Ely holdings at Ely, Nevada, by the Cole-Ryan interests, which have just secured an option upon all of the treasury stock and enough scattered shares to give them control, for 60 days, is significant, Mr. Ryan being president of the Amalgamated company. Another incident giving the proposition weight is found in the news received here that the International Smelting & Refining Co. is behind the building of a railroad from Goldfield to Ely, and thence to Salt Lake City and Tooele.

The Cole-Ryan people own the Giroux Consolidated, which abuts on the Butte & Ely claims, and both the Giroux and the Nevada Consolidated, on the other side of the Butte & Ely, have been sufficiently developed by underground openings up to the Butte & Ely's end lines, to indicate the value of the latter property. The option price has not been disclosed, but the stock rose on sales here from \$1.30 to \$2.10 per share, and the capitalization is but \$500,000, with the par value at \$1 per share. It is understood that the Butte & Ely, besides its 200 acres of patented ground, owns the one big and valuable water-right at Ely.

Direct information as to underground conditions in the North Butte is not obtainable here, but that those conditions are unsatisfactory to some degree is generally understood. It is stated by men who keep watch on mining affairs that the drifts on the 2000 and 2200-ft. levels have been somewhat disappointing, and the opinion prevails that the ore deposits on the lower levels may drop in richness to that of the general average in Butte. If this occurs it will lessen the dividends, and possibly reduce them to not much more than \$3 per share annually while copper remains at 13 cents.

Since acquiring the Giroux Consolidated at Ely, Nevada, the Cole-Ryan interests have started a second shaft on the Alpha from the 1000-ft. level and have finished about a third of it. The old shaft is down to the 1200-ft. level.

Robert C. Davis, superintendent of the Butte & Superior company, is quoted as saying that, "the new strike in Butte & Superior was made in the 1200-ft. level cross-cut about 300 ft. west of the shaft in the main vein. The cross-cut shows 20 ft. of high-grade zinc ore, the same as that opened up previously throughout the property, and is not through the vein yet. Included in this 20 ft. is a pay-streak of ore about 5 ft. wide, with from 5 to 10% copper. The drift west on this same level is now 200 ft. farther than the place from which this cross-cut was run. There is another

100 ft. to go on this drift before the end-line is reached. This will take two weeks."

Information received here from the Greenwater district in Nevada indicates that the camp is about deserted. The Greenwater & Death Valley Co. has been seriously considering the abandonment of its property, and the closing incident of the Patsy Clark copper investment known as the Furnace Range Co. was marked by the recent removal of the engine from the property. The one mine being operated full-handed is the Tecopa, which has been bought by the Graves Bros., of Philadelphia, white lead manufacturers, who contemplate erecting a small smelter near the mine.

The annual report of the Tuolumne company shows that the cash on hand on May 31, 1909, the close of the fiscal year, was \$79,103. During the year the company paid out \$30,512 for machinery and \$40,748 for wages and salaries. The income of the company amounted to \$189,801. The superintendent reports the addition of 400 ft. of shaft and 1615 ft. of other openings, and recommends the sinking of the shaft to the 2000-ft. level and the thorough prospecting of the levels on the way down.

TORONTO, CANADA.

Fire at Cobalt.—Shipments.—Montreal River.—Coal Miners Strike.

Cobalt was visited by a destructive fire on July 2, which destroyed some 200 flimsy wooden structures and rendered a large number of people homeless. Owing to the prompt and energetic measures taken for the relief of the sufferers, little hardship beyond the loss of property resulted, and the mining industry was not to any appreciable extent affected. The devastated area is largely situated on the Nipissing property, and advantage will be taken of the opportunity to explore the ground. When this section is re-built, restrictions will be imposed to prevent the recurrence of the calamity. The loss is estimated at from \$400,000 to \$500,000, with insurances totaling about \$100,000.

Ore shipments continue heavy, the record being again broken for the week ending July 3, with a total of 1016 tons. The heaviest shipper was the Nipissing, with 270 tons, closely followed by the Drummond with 240 tons, the La Rose occupying third place with 112 tons. The latter company has just disposed of the low-grade ore on its dump for \$300,000. An orebody 44 in. wide has been discovered in the Otisse. It is composed of two calcite veins with intervening rock impregnated with leaf silver. It was found in the north cross-cut between No. 1 shaft and the original Sam Otisse vein, and does not show on the surface. The Nova Scotia is having a slight boom in consequence of the finding of a vein 4 to 5 in. wide with rich silver content near the centre of the property, which was found in trenching and has been uncovered for about 90 ft. The company is now erecting a concentrator. At the Temiskaming a rich pay-shoot has been struck on the main vein at the 300-ft. level, the ore showing improvement as compared with the yield from the same shoot at the 200 and 250-ft. levels. The Badger lost its bunk-house, ore-house, and tank by a bush fire. The Kerr Lake Majestic has struck a 2-in. calcite-cobalt vein carrying native silver, on the 112-ft. level, 70 ft. distant from the main shaft. The Davis Silver Co., which holds 170 acres in the southeastern part of Coleman township, has adopted the leasing policy and has leased three properties on five-year agreements, on a 25% royalty basis. Operations are being vigorously conducted on these leaseholds, shafts being down on calcite veins showing silver to depths of 95, 85, and 65 ft., respectively.

Simultaneously with the news of the settlement of the protracted coal miners' strike in eastern British Columbia and western Alberta, where the men have gone back under open-shop conditions under a two-year agreement, comes the tidings of what promises to be a still more formidable industrial conflict between the Dominion Coal Co. of Nova Scotia and its employees. The question is primarily one of the recognition of the United Mine Workers of America, to which the majority of the men belong. This has been steadily refused by the company on the ground that, having its headquarters in the United States, it is practically a for-

eign organization. On the refusal of the company to negotiate, a strike was declared, and the men went out on the 6th. A large number belonging to the Provincial Workmen's Association, a local union not affiliated with the United Mine Workers, remained at work. There are conflicting statements as to the number on strike, but it appears that the total normal working force is 5200, and as the daily output has fallen from 12,000 to 4000 tons, probably the strikers number two-thirds of the whole. Some rioting having occurred, a military force of 500 men has been sent to Glace Bay, and martial law prevails.

BLACK HILLS, SOUTH DAKOTA.

Tin Mining to be Resumed —Harney Peak Receivership.—Spodumene Mining.

Much interest and considerable satisfaction attaches to the announcement that A. R. Ledoux of New York City has started active prospecting upon the tin claims of the old Harney Peak Tin Mining, Milling & Manufacturing Co., which some years ago 'operated' in the southern Black Hills. Had the operations of this company at that time been under the control of such a man as Mr. Ledoux, probably much more would now be known of the commercial possibilities of tin mining in the Black Hills, and it is this fact that gives a feeling of satisfaction at the announcement that he has found capital to back him in his investigation of the tin-bearing pegmatites and quartz veins upon those much abused properties. Owing to the interest which has always attached to the exploitation of tin deposits in this country, it will be worth while to recall some of the circumstances which attended the discovery of tin in the Black Hills and the existence of the Harney Peak company while it was 'mining' near Hill City.

Tin was first recognized as occurring in the Black Hills in 1876, when Richard Pearce of Denver identified cassiterite in placer gold from the northern part of the hills, and in 1877 Fred J. Cross discovered it in material from Elk gulch, in the southern hills. It was not found in place until June 1883, when A. J. Simmons of Rapid City sent specimens from the Etta mine, $1\frac{1}{2}$ miles south of Keystone, to San Francisco for determination. The Etta claim was at that time being prospected for mica. Shortly after this, tin was found in place at Nigger Hill, since called Tinton, but at that time well known for its rich gold placers, part of which had been discovered by colored men, whence the hill received its name. Soon after the discovery of tin at the Etta mine, in 1883, a number of companies was formed to mine the metal. These companies were finally consolidated into the Harney Peak Tin Mining, Milling & Manufacturing Co. English money to the amount of \$3,000,000 is said to have been sunk in the enterprise, and the amount of American money is unknown. Offices were established at Hill City, and a great number of claims, said to be about 1100, averaging 10 acres each, with a total area equal to 9 by 15 miles, were purchased, over a length of 30 and a breadth of 10 or 11 miles. According to stories told me by parties who sold claims to the company, but little showing of cassiterite was required to make claims salable at ridiculously high prices. Claims were perfunctorily examined, and vendors were busy hauling rock from claims carrying good ore to less rich properties, and in the lean dumps from the local prospect holes the imported ore was carefully arranged to catch the eye. Old residents say that bonds were taken upon properties offered for sale to the company, and when they came due the vendors were offered a much lower price, which was often accepted, and the deeds which were held in escrow turned over to the company's representative with figures unchanged, and presumably charged to the company at face value. One man told me of bonding claims to the company for \$15,000, and when the bond came due he was offered \$4000 for the property and papers as they were. He accepted, as he was afraid the boom was dwindling. Experts sent by the English stockholders to examine the properties were entertained, 'wined and dined', and shown the best shoots of ore. One man told me of being paid \$100 per day for eleven days to keep an 'expert' drunk, and the man suc-

ceeded so well that at the end of that time the 'expert' went back to England and gave a favorable report. Naturally such tactics could not keep the company going long unless there was a tremendous amount of extraordinarily rich ore at hand from which to draw, but it did last for several years. A number of examinations were made, mostly favorable for the company. It must not be supposed from what has been said that all the men who made examinations were either fools or rascals, for some of the men were of the best obtainable, but the ores are of such a nature that it is extremely difficult, if not impossible, to get an adequate idea of their average richness without actual mill tests of large tonnages.

Mills were put up about a mile east of Hill City and at the Etta mine, near Keystone, at a cost of many thousand dollars. The Etta mill alone is said to have cost \$235,000. Shaft-houses, boarding-houses, and other buildings necessary for large operations were put up on the Etta, Matteen, Gertie, Cowboy, Addie, Mohawk, Coates, and other claims; work was undertaken on a considerable scale, and thousands of tons of pegmatite were broken down. This was easily done, as the pegmatite may be drilled and blasted readily, and, lying, as it does, between schist foliae, it breaks with excellent smooth walls, and the high dip of the dikes makes stoping easy. Five thousand tons of ore which had been hauled from the various prospects was put through the mill in 1892 and yielded only one-fourth of one per cent of metallic tin. This was in great contrast with the estimates made by various men who had examined the properties, and was blamed to loss through unadjusted new machinery. Estimates had been made by different examiners, which ran from 1 to 6% of metallic tin, though the ones bearing most evidences of reliability were between 1 and 2%. The company went into the hands of a receiver in the summer of 1894, and remained under the control of the court until this spring. A large proportion of the claims were allowed to lapse, as they were not considered worth patenting. Others, about which the receiver had supposed there would be no question as to patentability, when money should be on hand to pay the expenses, are still unpatented, and have been attacked by the Forest Service as non-mineral lands. Almost the whole Black Hills region is in a forest reserve.

During the entire operation of this company probably less than five tons of metallic tin was produced—a less weight than that of the English money put into the venture (not to mention the American cash) would show if in the form of gold coin. What became of all this money? Undoubtedly a considerable sum was spent for claims, machinery, buildings, and mining, but if reports are to be believed, extravagance ran riot. A friend, who lived in Hill City at the time, told me that he one day met the general manager, now dead, who said to him: "———, do these fellows give you anything to drink here?" "Not much," replied my friend. "Well, I don't see why. I sent them \$200,000 a few weeks ago, and they have drunk it all up." Undoubtedly the language was more or less figurative, but locally it was the accepted way in which the company's money was supposed to be spent.

Since the collapse of the Harney Peak T. M., M. & M. Co., a little tin has been taken out of the placers, both at Nigger Hill (Tinton) and in the southern field. One company, the Tinton, has endeavored to work the lode deposits at Tinton, and several companies have attempted to work the Gertie claim, one of the claims allowed to lapse by the Harney Peak company, at Hill City. Litigation has made an already difficult situation worse, and little in the way of production has been accomplished at either place. Unluckily for the development of the properties, the court has allowed neither the leasing nor the working of the properties during the whole time of the receivership, with the exception of the Etta claim, on which tin was first discovered in place, and this has not been mined for tin, but for spodumene, a lithium mineral from which lithia salts were made. The spodumene crystals are immense, often 30 ft. long and 6 by 3 ft. in cross-section.

The mills show the effect of long idleness, and much of the machinery has been removed. It is to be hoped that Mr. Ledoux will develop enough ore to make these old mills shake their dusty joints and get to work.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Storage of coal under water prevents loss by oxidation. It thus retains the heating efficiency and serves to prevent spontaneous combustion. Shipment of coal at sea in flooded bunkers has been tried, and gas companies in Germany are now storing slack in flooded steel tanks. The average saving in combustible material by this system is reported by one gas company to amount to over 4 per cent.

Magnetic oxide of iron (Fe_3O_4) is formed to a small extent in copper smelting, and often appears in the matte, usually being more abundant in those of low than of high copper content. The slag, however, contains more of this substance than the matte. The method by which Fe_3O_4 is formed in smelting is still undetermined. It is commonly supposed to be formed in roasting, and subsequently to fail of being reduced in the smelting furnace.

Tuffs, representing volcanic rocks in a finely comminuted condition, are favorable for chemical reaction with waters traversing them. The complexity of composition promotes the chemical activity. Hence cases are known where tuffs in contact with limestone have been the precipitating agent for copper brought in by ascending solutions. Normally, contact copper deposits on the borders of limestone beds would occur in the lime rather than in the rock of igneous origin.

Gold in the lower desert portions of California is commonly associated with tungsten minerals, while tourmaline is generally absent. Tungsten is particularly in evidence at Randsburg, where extensive mining operations have been conducted for many years by the Yellow Aster company. It is also found in the old Amalie district, in the Tehachapi mountains, and in the veins around Silver mountain, near Victorville, where renewed activity is taking place. These are all in granitic areas, intruded by eruptives, mostly trachytes, with some andesites.

Concentration of slime varies according to the physical character of the pulp. The degree of fineness of the pulp, the amount of alumina in the form of kaolin, the quantity of sericite, and of colloids, exercise an important influence. Efficiency of concentration of slime is dependent upon the rate of settling of particles of the concentrate through the pulp, diluted to the extent required for treatment on tables or vanners, but the rate of settling is not necessarily a function of the specific gravity of the pulp. There are interferences of a complex nature which have been only imperfectly studied.

Retort reduction of quicksilver ores has been almost universally superseded by treatment in shaft furnaces, fitted with shelves for feeding the ore from the side, owing to the extremely limited capacity of retorts. The disadvantage of direct-firing is the great volume of heated gas to be cooled, and the soot and other solid matter in the fume, upon which

quicksilver is condensed and carried out into the atmosphere. The flue-gases are cooled to 60°C . Rotary furnaces will soon be in operation in California, and experiments are being tried with electric furnaces, heating tile-supports with resistance coils, so as to dispense entirely with furnace gases. The latter plan is being worked out by H. C. Davey of Los Gatos, California.

A lode-claim is located by C, who describes it as being 1500 ft. long, and as being bounded on the south end by the claim of D. It is, in fact, less than 1500 ft. long. D later abandons his claim. Can C amend by including enough ground from D's abandoned claim to make a full claim, no adverse rights having attached? The ground embraced in D's location was rendered open to location by his abandonment, and C could locate the whole of it as a new location, or incorporate a part of it in his existing claim by amendment.

Bornite is stated to have been found as an original constituent of certain gabbros, but this is open to doubt. Not only may bornite be formed by reaction between pyrite and copper salts disseminated by diffusion through a rock, but it will form in films of such infinitesimal thinness on the parting planes of pyrite and pyrrhotite that the crystals will possess the lustre of bornite, no matter how finely they be broken. Rocks containing pyrrhotite usually carry copper also, and it is well to test suspected bornite in such situations with a magnet. As small a quantity as 0.2% copper will stain pyrrhotite so that it will appear to be pure bornite.

Settling of sand from pulp may be facilitated by causing the pulp to flow through launders the depth of which is great compared with their width. The lower two-thirds of the launder should be fitted with baffle-boards with 2-in. spaces between, inclined at an angle of 60° in a direction opposite to that of the flow. The settled sand should discharge continuously by siphons placed at intervals along the length of launder. The principle of the settler consists in the formation of eddies at the head of each compartment, out of which the sand settles upon the board and then slides to the bottom, undisturbed by currents in the surrounding water.

Can two lode mining claims, located along the strike of the same vein, be based upon a single discovery made at the point where the vein crosses the common end line? This question has never been authoritatively decided by the courts. The view of the Land Department and the best opinion of text writers on the subject, however, is that a discovery must be viewed as an entirety, and that a single discovery cannot support two mining claims. Both claims, therefore, cannot be valid, but it may be that the locator or locators would have the right to elect upon which of the two claims to credit the discovery, and that one of the claims might be upheld. The safer method, however, is for the locator to make an independent discovery entirely within the limits of each claim. If either claim is void for lack of discovery, the ground embraced therein is, of course, open to location.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

What Is an Ore?

The Editor:

Sir—I am loath to enter the arena to discuss geology with the man from whom I learned all the geology I know. I am sure that I am only one of a host of engineers who read J. F. Kemp's articles with avidity, in my case increased by a keen sense of all I have forgotten in the fourteen years since I heard the sound of his voice in the lecture-room. The paper on 'What Is an Ore?' brings home very forcibly the elusiveness of our ideas on the subject. We have always been ready to give a definition of 'ore'. The number of authorities quoted by Mr. Kemp shows how inexact and varied are these definitions. I desire to offer a suggestion, and I assure you that my knowledge of Mr. Kemp's kindly character does not lessen the trepidity I have in doing so.

He states that "use is the law of language." By which we understand, that in defining a word the correct value is that placed on it by the persons most familiar with it. On that basis, it seems to me that the conclusion that "the test of profit" meets the requirement of a standard, is unsatisfactory. Comparing the various definitions quoted in the paper, we find the subjects approached from several standpoints. Some of them can be left out of further consideration, but there are two classes, representing two different ideas, which are worthy of further consideration. One class is that advocated by Mr. Kemp, and takes as the absolute standard what may be termed the metallurgical viewpoint, namely, the ability to treat the stuff at a profit. The other is that represented by the definitions of Van Cotta, Stretch, and Louis, in which the test of profit is not the sole criterion. Stretch's definition, in my opinion, conforms more nearly than any of the others to the generally accepted usage of every-day mining life. He says: "Among miners, whatever will pay to treat, or ship and sell, is considered ore, as also low-grade mineral which might be utilized by concentration or improved facilities, but there is an indefinite shading off into material containing traces of ore minerals but hopelessly unavailable, and this would not be considered ore." The objection Mr. Kemp makes to this and some other definitions, is that a shifting standard is introduced. That no doubt is true, but the question that presents itself is: Can a satisfactory standard be established by means of which the word can be defined upon a 'secure and unmistakable basis'? By this, it is to be presumed, it should be so unmistakable that even the veriest novice would be able to know ore. In attempting to do this, I think we are immediately confronted with the impossible. So far as my experience goes, the generally accepted sense of the word ore, among miners, cannot be enclosed in a ring fence. It is elusive to the point of shading off into mineralized country rock.

Before proceeding let us enquire into the exact intention of Mr. Kemp's expression when he states, "capable of being won at a profit." The whole definition hinges on the word 'capable'. It surely is open to all the objections of indefiniteness that have been raised against some of the other quotations. Does he mean, capable of being won at a profit anywhere in the world, or at the particular mine under discussion? Are we limited as to time, or does it exclude the question of time? Near the bottom of page 419, second column, we read: "Is not 20% iron considerable, yet it would not warrant mining? Is 0.0008% considerable, yet it might justify mining for gold?" In the first portion of this quotation it would appear that he does not intend any limitation as to situation; in the second, rather the opposite is implied. In neither case does it appear that "the test of profit" is an "unmistakable standard," and the indefiniteness of the word 'capable' is likewise exemplified. In the succeeding paragraphs I will attempt to show, by a series of examples, that "the test of profit" from the miner's standpoint does not meet the requirements of a standard.

Mr. Kemp states: "In a new enterprise, as we all know, it is customary to refer to the mineral in the ground as 'ore', before it is proved to be such by profitable operation." Is it not a fact that this is by no means limited to new enterprises, but is used in connection with old ones as well? The average miner differentiates between ore and country rock, further classifying the former as payable and unpayable. It is a matter of common usage to speak of filling stopes with low-grade ore, meaning thereby that portion of the orebody that does not pay to raise to the surface. Engineers the world over, in valuing mines take into their calculations as 'ore', material that of itself is nowhere capable of being won at a profit, much less at the mine they are valuing. They speak of the limits of the ore-shoot, as representing that portion of the orebody which under existing commercial conditions will pay to mine. That portion of the vein or lode outside the ore-shoot which carries values, even though the values be unpayable, they are likely to describe as low-grade ore. This is a world-wide custom in mining districts where English is spoken, and to my mind is enough to throw out the "test of profit" basis. In the strictest sense of Mr. Kemp's definition, two adjoining mines, working exactly the same ore, one at a profit and one at a loss, would be yielding ore only where working at a profit. We know of the recent great reduction in working costs on the Rand, rendering available for treatment a large quantity of quartz that hitherto was considered unpayable. In the same issue of your paper, in an editorial you speak of the 'ore' reserves of these very mines having been increased by this reduction of working costs. Ore reserves cannot be increased except by ore. If it is ore today, was it not ore yesterday, at least from the miner's standpoint, if not from the metallurgist's?

An aspect that should not be overlooked is the question of impurities in varying percentages, that interfere with profitable working. Near Zeehan, Tasmania, is a mine containing a large deposit of mixed lead, copper, and zinc sulphides carrying silver. The

greater part of this deposit is not being mined on account of treatment difficulties. Despite the fact that the treatment trouble has not been overcome, every engineer who has seen the mine would speak of this at present unpayable mineral as 'ore'. The San Francisco del Oro mine in Mexico has a shoot of ore of great length, but it likewise has not been mined at a profit because of metallurgical difficulties. From the metallurgist's standpoint, the material in the vein may not be ore, but a number of engineers of repute have gone on record, describing the mineral as 'ore', and by the miner it would unquestionably be called ore, despite the fact that it nowhere has been won at a profit. Again, we have a mine containing ounce gold 'ore', yet the physical conditions are such that it cannot be mined at a profit. Ounce gold ore would be considered high grade in most places. At the Spanish mine in California I believe that some years ago they mined and milled at a profit gold ore that only yielded 75c. per ton. Therefore, in the broadest sense of Mr. Kemp's definition, "capable of being won at a profit," we may say that any quartz carrying ¾ dwt. per ton is 'ore'. However, without cavil, I may say that most mining men would not so denominate a quartz body of that value. Despite the unprofitable character of the former as compared to the latter, no miner would hesitate to call ounce ore 'ore', whether it happened to be payable or not.

The case of the great Mt. Lyell mine is worthy of note. The present company is a consolidation of the old Mt. Lyell company and the North Mt. Lyell company. They had been unimportant producers prior to the year 1903, but increasing metallurgical difficulties threatened the ruin of both concerns. The matter was entirely one of the proper fluxing of the ores. The Mt. Lyell mine is an enormous deposit of pyrite containing copper. As long as they were able to get suitable acid fluxes from the other mines they controlled, all went well. The North Mt. Lyell mine ore used to average about 8 to 10% of copper, but it is silicious. As long as they were able to get suitable basic fluxes, all went well with them also. The time came with each property when the flux question became very serious, and unless a suitable smelting mixture was obtainable, both mines must shut down. It will be recalled that in 1903 the price of copper was low. Since the date of the consolidation, namely, August 10, 1903, until September 1908, there have been treated the following tonnages:

| | Tonnage. | Assays | | |
|---|-----------|--------|---------|---------|
| | | Cu, % | Ag, oz. | Au, oz. |
| Mt. Lyell Mine | 1,463,244 | 0.91 | 1.89 | 0.071 |
| North Mt. Lyell and Lyell Tharsis | 583,920 | 6.08 | 1.72 | 0.0052 |

A total of 2,047,164 tons of 'ore'.

The ore reserves are stated to be:

| | Tonnage. | Assays | | |
|-----------------------|-----------|--------|---------|---------|
| | | Cu, % | Ag, oz. | Au, oz. |
| Mt. Lyell Mine | 3,382,117 | 0.54 | 1.96 | 0.030 |
| North Mt. Lyell | 710,333 | 5.75 | 1.33 | 0.005 |

That statement goes unchallenged by the mining community, as does the statement of the tonnage of 'ore' treated. I cannot imagine even Mr. Kemp denying that this mineral is and was ore, although either one may be incapable of being won at a profit under

the conditions usually prevailing at Mt. Lyell. Whatever one may say regarding the pyritic orebody, which now averages only 0.54% copper, against about 1% at the time of the consolidation, it is certain that no one will gainsay that the mineral making up the tonnage and value of the North Mt. Lyell ore is 'ore'.

To quote only one other instance of the numerous examples that may be cited: the low-grade copper deposits of Nevada were for a long time not classed as ores, and with reason. Notwithstanding their successful exploitation in Nevada, material of that character would not ordinarily be classed as ore, unless existing under similar conditions.

Mr. Kemp in quoting Louis' definition, comments as follows: "If you saw a pile of magnetite at a blast-furnace, being successfully treated, you would call it an ore, even though it had been bought at the bankrupt sale of some miner." He is entirely right, and he sums up the consensus of mining opinion in that statement. The material is 'ore', despite the fact that the miner was unable to make a profit out of it. I submit that Mr. Kemp's "test of profit" does not meet the requirement of a technical definition, except from the standpoint of the metallurgist. And even the metallurgist sometimes gets ore that he cannot treat at a profit. The closing down of the Ponderay smelter within the last few months, because it could not compete with smelters more favorably situated, may be instanced. On the other hand, geological considerations, as well as commercial and physical conditions, affect the miner's standpoint. These include a number of factors, with an almost infinite number of variations, rendering it practically impossible to put into words any exact definition. By which I mean, one which may be applied to any condition that may be met.

The geological consideration, a point that has scarcely been touched by any of the authorities, is one of the first importance to the miner, because the nature of the concentration of the minerals in their native state has an important effect on his attitude. Therefore Van Cotta's description that "Under the general term ore are comprehended all minerals or mineral aggregates which from their metallic contents attract the attention of the miner," has a great deal of merit. If we can make plain what 'attracts' the attention of the miner, we will have an ideal definition. It may be taken as an axiom that the incentive to the miner to work is the profit. It is for this reason that he prospects and develops and exploits a mineral deposit. But once he is 'attracted', the question of profit does not limit his application of the term. He may cease operations when he has no more pay ore, or he may continue his work in unpayable ore, in the hope that his brother, the metallurgist, may find some way of enabling him to make a profit out of the low-grade material. However, as soon as he finds a portion of his deposit amenable to profitable exploitation, he will undoubtedly include under the heading 'ore' a large amount of material that of itself will not yield a profit. His underlying idea, perhaps, is that the discovery of some higher grade material which can be used as a sweetener will enable him to mine his low-grade stuff. The whole question on this basis no doubt resolves itself into a very in-

definite position, but, as already pointed out, I do not think that we can restrict the definition solely to "the test of profit." A broader, if more inexact, basis must be allowed, one which perhaps takes account of personal equation, but which will satisfy the primary fact that "use is the law of language."

I hesitate seriously to offer a substitute for a definition given by so eminent a scientist, yet, for fear of being accused of destructive criticism, I would suggest that, for technical use, the word 'ore' be defined as follows: A metalliferous mineral, or an aggregate of metalliferous minerals, more or less mixed with gangue, that from the standpoint of the metallurgist can be treated at a profit, or that from the standpoint of the miner occurs in a vein, lode, or other geological deposit, and concentrated by nature in such a manner as to attract the attention of the miner, on account of his belief that he can work at least a portion of such deposit at a profit.

There is no doubt a variable factor in this definition, namely, the 'belief' of the miner, but it permits one having a knowledge of the subject to make a fairly accurate estimate of "What Is an Ore?"

La Libertad, Nicaragua, May 20.

Santa Eulalia Camp.

The Editor:

Sir—In your issue of July 3, Louis Lane of Chihuahua takes exception to my article on Santa Eulalia as containing numerous errors of statement. Most of these alleged errors he disposes of collectively, apparently not feeling enough interest in the readers of the 'Press' to guide them to the exact truth. In regard to the points which he itemizes, no one could be more appreciative of any contributions to the sum of human knowledge than myself. As to the average value of the ores being exported from Santa Eulalia in February 1908, the time of my visit, my statement is based on information received from several successful mine operators of the district, whose names can be given if necessary. Of ores in reserve I have no knowledge, although I was aware that occasional masses of rich ore had been found. It is to be hoped that Mr. Lane, with the possibilities of more complete knowledge, will give an extended record of the values carried by average ores from the different mines. His point about silver having a higher gold-value in the 18th century than at present, is well taken, as well as his expression on the cost of labor, but we must not forget that the methods of metallurgical treatment were then very wasteful. Probably in the primitive furnaces used in Spanish days not more than 50% of the metals were recovered. It is, I believe, a fact beyond the possibility of controversy that the old slag dumps of the Santa Eulalia furnaces were for many years worked as a placer field for silver globules which had been locked up in the slags and released by the action of the weather.

As to the origin of the limestone conglomerate, in regard to which Mr. Lane differs with me, that must remain a matter of judgment. Of the faulting, there can be no question. The greater fault I mention was observed by Robert T. Hill. Kimball's observation

on the dip of the strata is given solely on his authority, as I had not time to verify it. The statement regarding Sierra Mojada, though confusing to Mr. Lane, may not be so to all. In conclusion I would say, with some regret, that Mr. Lane appears to belong to those who rest in enjoyment of their information, only caring to speak when someone, attempting to help his fellows, and publishing the best facts he can obtain, falls a little short of complete accuracy. If my critic would make public all available accurate information on Santa Eulalia, he would be a true benefactor.

New York, July 8.

F. J. H. MERRILL.

Civil Service Reform.

The Editor:

Sir—The editorial entitled 'Civil Service Reform' in your issue of July 10 admits of criticism since, rightly or wrongly, the opinions there expressed may be considered reactionary. Reduced to its elements, your proposal is to strengthen the hands of departmental chiefs, giving full managerial responsibility. As a means to this end you propose that the bureau chief be empowered to select and discharge employees. The selection would of course be made from those constituted as eligible by success in passing the Civil Service examinations. Discharge would be 'for cause', at the discretion of the responsible head. The effect of such a system would be to create a new dispenser of patronage, in place of the congressman of earlier days. It would exaggerate the importance of these officials, and convert their posts into coveted political plums. The familiar college expedient of 'boning' for examination would be applied, with all its absurdities and tricks, to give a candidate for a clerical position that status which would enable his appointment to be made. The incompetency resulting from unrestrained favoritism might not exist as in the past when the spoils system prevailed, but the proposed method would be open to grave abuses. It assumes also that a manager can select men by some power of insight deeper than a system of rigid examination. Superior vision of this sort few men possess. There is no more difficult thing than to pre-judge human character and capability. The man who can do it rises speedily above the level of a bureau chief.

Long experience in management has shown me, and I am certain it must have shown the same to many, that the power to select subordinates is not the prime requisite for successful administration. Given any rational system of honest enquiry into character and attainments, the chances of drawing efficient men are excellent. The real disciplinary power lies in the right to dismiss from service without appeal. Winnowing conducted by such a method will soon yield an active and capable corps. But the power of free selection, even from a list of eligibles, would infallibly restore the evil of favoritism. The Civil Service should establish the rank of eligibles as to grade of efficiency and priority, and they should be available in that order and not otherwise.

San Francisco, July 19.

MINING IN NORTHERN SINALOA, MEXICO.

Written for the MINING AND SCIENTIFIC PRESS

By E. A. H. TAYS.

Outside of a strip of land, averaging 40 miles wide, parallel to the coast, the State of Sinaloa, Mexico, consists of country which in the United States would be classified as mineral land. The east boundary does not reach the Sierra Madre proper, though many ridges reach 4500 ft. above sea-level; the formation therefore is open for inspection, that is, it is not buried by hundreds of feet of tuff, as is a large part of the main Sierra range. This makes prospecting easy, and as there is here a zone 40 miles wide on each side of the Sinaloa east boundary line, well

ing it may be, if it does not promise to pay daily wages from the start.

A number of prospects are being developed and, at times, considerable ore is shipped, but shipping is restricted by the fact that it takes \$50 ore to pay. The new railroad will better this condition materially, and will also help to start the general development of the mineral resources of the West Coast. The line extends along the western limit of the mineral belt. The districts of Fuerte and Sinaloa are rich in precious metal veins, from the Southern Pacific railroad line, east to the State line. From the time one crosses the Sonora line into Sinaloa mineralization is apparent on every side. The railroad runs by the main shaft of the old Sivirijoa silver

Northern Sinaloa, Mexico.

mineralized and practically virgin, running in a southeasterly direction for 50 miles, one can readily see that this section holds great opportunity for prospectors. The northern part of the State of Sinaloa, which is covered by this article, embraces the districts of Fuerte and Sinaloa. I have said that this section is practically virgin, and it is true, despite the fact that one rarely sees a vein that fails to show some signs of someone having been there before.

Much prospecting has been done in years gone by, but little development made of any of the many veins to be found. The reason is that the native Mexican prospector does this kind of work as a means of earning his daily bread, and though he incidentally seeks new veins, his main object is bullion; he has little use for a vein, however encourag-

ing it may be, if it does not promise to pay daily wages from the start. The country is open and rolling, with a few isolated hills in the vicinity, none of which reach 350 ft. above sea-level. The formation in the immediate vicinity of the vein is a tufaceous agglomerate, probably andesitic; what the depth of this may be is hard to tell, but it will probably exceed 300 ft., and it apparently rests on grano-diorite. The whole plain for several miles around Sivirijoa is cut by seams and veins, and this condition extends to the river, 20 km. to the east. The railroad has a station at Cañedo, in the centre of the zone.

Just across the river from San Blas, where the Southern Pacific crosses the Kansas City, Mexico & Orient railroad, is an exceptionally prolific zone, on the Buena Vista ranch. The formation is grano-diorite on the north and rhyolite on the south. Here veins of good size are found every half mile, showing a trace of gold and a small amount of copper. Where 2 to 3% of copper is incased in 80% of silver, it usually stays there. There is one promising vein in this zone, the Aquincuare, but it is tied up in a lawsuit. There are a number of lodes in the mountains just east and northeast of San

Blas. On the west side the general content is copper, mostly carbonate, but with a fair sprinkling of sulphides. In some of these is to be found lead carbonate and a little silver. On the east side are some lead-silver veins, and a few are to be found showing a little gold. The formation runs from a silicious metamorphosed porphyry to recognizable rhyolite.

Up the river there is not much until Fuerte is reached. Between Fuerte and Choix, a famous old copper-producing town, granite is the predominating rock. East of Fuerte, to the eastern boundary of the district, is the gold zone of northern Sinaloa, both lode and placer. At Realito, 14 miles east of Fuerte, are found numerous veins all assaying a little gold, and all having indications that induce development. Some placer gold is found in this district, but nothing on a commercial scale. The rocks are schistose, but

undoubtedly of igneous origin. Farther east, at Chinobampo, granite is in evidence again. In the Yecorato region is found the only placer ground that promises to be of sufficient size to admit of large operations. Here the arroyo for several miles contains gold, with water enough to permit of dredging. Most of this is now held by an American company which is at work; but, with the methods pursued, it seems doomed to failure, in spite of the fact of there being gold in 'commercial' quantity.

Around Yecorato the underlying rock is granite, with andesites and rhyolites overlying this. In places are large stretches of andesite, especially to the south. Northeast of Yecorato, about eight miles distant, is the Minitas region. Here the granite is the main country rock. It is cut by numerous veins that contain gold; but where these are not small in size, the ore is 'spotty', and nothing of a formal nature has been developed in this region, although a small amount of gold is being shipped continually. To the east and south of Yecorato, for miles, is a great andesite zone, and around Potrero are found several large veins, some containing gold, and others lead-silver and zinc.

In time Choix will be the centre of a large zone of mining activity. To the north and east of Choix is a great granite belt cut by numerous dikes of andesite and rhyolite, and, in places, it is overlaid by an overflow of these rocks, or by isolated layers of other eruptives. In the northern part of this zone is the gold-silver-copper zone of Las Papas. Near the Fuerte river, in the same region, on the Lo de Castro ranch, gold and copper are found. The formation here, in places, is lime, generally in isolated fragments lying on the crests of the andesite intrusions that tore them from their original position. There is here much mineralization, the veins containing mostly copper and gold. Between Choix and Bacayopa is a country showing signs of much volcanic activity, though some lime in place is found in a few localities. These and the intrusive andesites and diorites lie on the great granite base. Here the prospector will find a mineral region that will undoubtedly repay labor expended in the endeavor to 'make a mine'.

Lying to the south of the Fuerte district is the Sinaloa, cutting across the coast-range mineral belt. Gold is here the principal metal. From the old stage road eastward there is hardly a ranch that has not a vein. Right in the town of Sinaloa are found gold-bearing stringers in a schistose igneous rock. Bacubirito can be called the centre of the mineral belt that covers practically two-thirds of the Sinaloa district, and part of Mocorito and Badiraguato. To the north of Bacubirito some thin-bedded limestones are found; and along the State boundary with Chihuahua some granite and lime, and, in isolated spots, metamorphosed schists, with here and there the lower granite showing over extended areas, but, for the most part, the whole region consists of andesite and rhyolite flows, and the breccias of these and other rocks. To the south and west of Bacubirito is the great Mapiri zone, where pockets are found with sufficient frequency to keep the region fresh in every one's mind. However, nothing of any great value so far has been developed. Around the base of this isolated range

much placer gold is found, usually in nuggets. These vary from the size of a grain of corn to masses of 30 oz. However, though placer gold in small quantities is found everywhere, there seems to be no single body of gravel sufficiently large or rich to warrant great expenditure.

The Sinaloa river below Bacubirito should contain considerable placer gold, but the bed is probably so littered with big boulders that dredging operations would be futile. At this place the river makes a bend of 14 km., and comes back to within 200 m. of itself, there being a fall of 100 ft. between the two points. Here is a chance for a hydro-electric installation.

East of Bacubirito the mountains rise to considerable heights, the La Joya peaks in the Ocorahui range being probably 5000 ft. above sea-level. Most of the veins here contain silver as the predominating metal, with considerable copper. North of Bacubirito, 30 miles, is the camp of San José de Gracia, yielding gold. The main formation is andesite, though rhyolite and diorite are also found. This camp has been in operation since 1836, and is one of the most important in the State. Since 1894 modern mills have been operated, and two of the mines, the Jesus Maria and the Rosario, have conjointly shipped, approximately, \$10,000,000 in gold bullion. These veins are not large, but are fairly rich. In this zone are many veins awaiting exploration, some of which promise to turn out as well as their neighbors. To the west of San José de Gracia some 30 miles, is the Cuitaboca zone, yielding silver. The formation here is entirely unaltered andesite. The veins are large, and some of them are sure to develop good orebodies. Only two have been worked, namely, San Antonio and Jesus Maria. The ores are somewhat 'rebellious', but contain from 45 to 70 oz. silver per ton. This region joins the Fuerte district to the north, some 20 miles away.

North of Ocoroni, on the Santa Ana and Tetache ranches, is a practically unexplored zone that promises to respond favorably to prospecting. Nearer the coast are a few isolated ranges on the Tetamecha ranch that also promise much, as many large veins are known to exist. As the Southern Pacific railroad now skirts along the entire west side of the region discussed, and as there are several large valleys running up into the mountains, with trails in every direction, it will be seen that the country is extremely easy of access. One can now leave Denver or San Francisco and in five days time be in the heart of this mineral belt, with no hardships that are worthy of mention.

Tungsten deposits occur in the Black Hills at several places, but have been exploited commercially only at Lead, in the central hills. The valuable ore is wolframite. Tungsten is of especial interest and value in connection with its use in tool steel and as a filament in incandescent electric lamps.

Tin deposits occur in the northern part of the Black Hills of South Dakota at Tinton, and in the southern part near Hill City, Oreville, and Custer. The geology of the deposits has been discussed recently by F. L. Hess, of the U. S. Geological Survey.

PLACERS OF WALDO, SOUTH OREGON.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN M. NICOL.

In the early days the camps of Waldo and Kirby were among the most famous of south Oregon, and apparently reliable estimates place the output of the Waldo district at eighteen million dollars. The only placers of importance which are still being worked are known as the Simmonds, owned by J. T. Logan, and the Weimers, owned by the Deep Gravel Mines. There is also a high bench or old river channel known as Al. Adams placer, which owing to lack of water is only worked to a limited extent. The district is one of numerous beautiful grassy glades, and little flat-bottomed valleys, which wind among a series of low rounded foot-hills, which are in turn flanked by mountains, snow-clad late into the summer months. These mountains form the boundary between Cali-

Logan Placer Mine, Waldo, Oregon.

original topography apparently consisted of wide, deep, and fairly level valleys, which as a result of some change in the drainage plane of the country gradually silted up. The thickness of the deposits varies from a few feet to 150, and the width from a hundred feet or so to several hundred yards. Practically all of the virgin gravels of the district are below the natural drainage plane, and would therefore have to be worked either by driving, by mechanical or hydraulic elevating, or by dredging. The gravel consists of boulders and pebbles from 10 in. diam., down to the finest sands and clays. A most interesting feature, and one worthy of note, is that nearly all of the coarse gravel, and in many places the so-called bedrock conglomerates, are completely decomposed and friable, so that they can be readily disintegrated with a hydraulic giant. The coarse gravel is very evenly distributed over all of the lower parts of the bedrock, and its thickness varies from a few feet up

to 10 or 20. It carries the greater part of the gold and platinum. The overburden consists of finer gravels and some sand, though the bulk of the material is fine sub-angular grit and clay. Handling the large percentage of clay found throughout the deposit is one of the serious problems, both in mining and in gold saving.

The upper and shallower part of the Weimer placer was worked to a considerable extent by a long race, which was excavated by giants, and which discharged into the west fork of Illinois river. Subsequently a considerable body of gravel was mined by Hendy hydraulic elevators until the depth of the gravel penetrated was greater than could be mined with the pressure available. J. T. Logan has taken advantage of two different ditch lines, with different heads to place two elevators in tandem, and by this means

he is enabled to work the deeper gravels. One of the hydraulic elevators has a lift of 39 ft., and operating with a head of 330 ft., uses 11 cu. ft. of water per second, besides taking all the water from two No. 2 giants. The second elevator has a lift of 9 ft., a head of 125, and uses 18 cu. ft. of water per second, besides all the water from the first elevator. This makes the final discharge about 40 cu. ft. per second.

The largest proportion of the gold found is fine and a great deal of it is coated with a film of what is stated to be palladium, and which effectually prevents amalgamation. When a clean-up of the sluice-boxes is made a great quantity of rounded and sub-angular fragments of hematite are found in the riffles, varying from the size of a large pea down to the finest red mud. I collected samples of this, and after screening out the fine material below 40 mesh, and carefully hand-picking the grains to remove any small nuggets of gold, I had the residue assayed. The assays showed that all of this hematite contains considerable gold, platinum, and osmium-iridium. The samples from the small gulches and old benches

fornia and Oregon, and are the source of water supply for the mines. In the spring when the wild azaleas are in full bloom, the charm of the scenery is so great that the engineer, if not the miner, is apt to forget the problem in hand, and to regret that these beautiful green glades must be torn up and washed away to win a few pounds of precious metal. All the flat-bottomed valleys are placers, varying in depth, extent, and richness, but all carrying some gold and a considerable proportion of platinum. The problem in prospecting at Waldo is not to find a placer, or a rich streak, there being probably several million cubic yards of virgin gravel, which contain 20c. per yard; the difficulties faced are in finding methods of working the known deposits economically and at a profit.

The rocks which are most in evidence in the district are serpentine and slate, though there are some fairly large masses of porphyry and some intrusives. In working the low-lying placers, a so-called bedrock has been exposed at a number of places. It is a decomposed conglomerate, the remains of an underlying placer much older than those now worked. The

Deep Gravel Mines, Waldo, Oregon.

Logan Placer Mine, Waldo, Oregon.

were the richest. I found some that would assay from \$200 to \$500 per ton of included gold, platinum, and osmium-iridium. The average of several samples that I took from the sluices of the Deep Gravel Mines gave \$40 per ton.

Whether it would pay to save this product depends upon the proportion per cubic yard; no proper tests have been made to determine this. I made estimates from pan tests that the amount would be from 2 to 10 lb. per cubic yard of gravel. This from a placer yielding 500 yd. per day would give from $\frac{1}{2}$ to $2\frac{1}{2}$ tons of concentrate of hematite. These values would seem to warrant investigation as to the possibility of saving some of the concentrate.

MR. MURPHY ON CONTINGENT FEES.

Written for the MINING AND SCIENTIFIC PRESS
By AN OCCASIONAL CONTRIBUTOR.

"I tell ye, McCarthy," Murphy said one day as they were coming off shift together, "that 'twill not be long now befor ye c'n buy mining stocks with th' sa-ame ca-am sinse iv sayeurity that ye wud feel fr'm puttin' ye-er money in th' Hibernia Savin's Ba-ank out on Ma-arket Strate."

"How is thot?" asked McCarthy.

"Why! don't ye ra-ade th' la-ad Ricka-ard's pap'r anny more? Th' wan that me frind with the purty na-ame Coortenay De Kalb Bain's runnin' now, as a squarehead wud say it. Ye-er not up t' da-ate at all, f'r ye don't know that th' la-ad Cha-ance that I told ye av wance befor, has bin gettin' his bys thegither into a flyin' widge so as t' bra-ake up th' interfere-ence iv th' Nevady la'ads, that seem t' be gettin' away with th' money. Grate excitemint has prevailed. Th' prosaydin's have bin rayported t' be wireless—th' kind that ta-akes th' two cint sta-amps—all over th' world; f'h th' bys have wanted their frinds t' rade what they said.

"It was raysolved an' daysided amid grate applause, that th' tarm 'contingent fay' is a most haynouns one, an' that hereafter it shall be called an honoraryum, excipt in a few speshul ca-ases. Wan iv thim is, that you'll be allowed t' ta-ake th' cement la-ands iv unprotieted feemales, under th' fo-orms av th' contingent fay, f'r ye cud hardly call this an honoraryum. Anither is, if ye can-an't git a la-ad t' pa-ay ye th' full bet annyhow, no matther if it comes heads or tails, ye c'n ta-ake what ye c'n git, with a promise f'r th' rist if ye c'n ma-ake a good raypoort."

"It is also daysided afther a long dayscushun, that full raypoorts must be ma-ade iv everything ye do that raysults in operayshuns. If a mule squeezes over an' stips on th' foreman's feet whin he is tryin' t' crowd past in th' drift, th' raypoort must say so; f'r th' la-ad is apt not t' clime up t' th' back of th' stope, an th' Gra-ake la-ad Papaeruckus may git away with some pyri-ite he thinks is th' pure quill. 'Tis a most scholarly dayscushun, f'r th' la-ads had all bin brushin' up their larnin'. Th' by Gent put across a foine bit iv Frinch, which mint t' ta-ake a tra-ace an folly up th' la-ad who got afther th' windmills, an' ta-ake a fall out iv th' hot-air performers. This created gra-ate applause till th' la-ad Wright, who c'n peddle th' bull himself, came back with a bit in

Latin, statin' there was a hole in th' argymint, or 'twas no sich thing, or wor-rds t' that effect. This created more applause, f'r th' la-ads had bin radin' fr'm their own note-books in outlinin' their suppositious ca-ases, an' it pla-azed thim t' think that maybe they'd not done so wrong afther all. 'Tis not wrong t' ta-ake th' money iv th' farmer,' says th' la-ad Finlay, an' nearly iverywan does a little farmin'. Minin' is a sa-afe gamble alongside iv placin' all ye-er bets on th' weather. Th' la-ad Munroe must have bin stung har-rd, f'r he breaks in an says, 'ye c'n trust nobody,' he says, 'not even yer best frinds,' he says, 'an' th' only way t' bate th' ga-ame is t' dale it ye-ersilf,' says he, 'an use a trained box,' he says, 'an' thin ye ca-an't be sure'.

"'Tis finally daysided that if everywan wud be honest an' obey th' Golden Rule, an' niver ma-ake a mista-ake, that condishuns wud be much improved, an' so th' resolushun is adopted, that hereafther such will be th' ca-ase. 'Tis a grate victhyry f'r th' la-ads that wanted t' let bygones be bygones."

"Well, what was all th' dayscushun for?" asked McCarthy.

"If ye raley want t' know," said Murphy, 'th dayscushun was chafely be th' la-ads that are now livin' aisy on th' dividends fr'm a few long shots they took in their arly days, an' should have bin entitled, 'How t' git away with th' contingeft fay an' kape a clear conscience'."

Cracker Creek mining district, in the northwestern part of Baker county, Oregon, is a small part of the Blue Mountain gold belt of the State, but as generally defined comprises the drainage basins of Cracker and Fruit creeks. The principal mines in this district are the North Pole, Eureka, Excelsior, Columbia, and Golconda, all situated, from northwest to southwest, in the order named, on one persistent fissure, the North Pole-Columbia vein, or 'mother lode', as it is locally designated. The aggregate production of the mines on this lode is estimated to be at least \$7,000,000. At present the Columbia is the only producing mine in the district, but the suspension of operations in most of the others is believed to be temporary and not caused by exhaustion of the orebodies. In addition to the mines above mentioned there are a number of smaller mines and prospects on which annual assessment and considerable development work is being done. J. T. Pardee, of the U. S. Geological Survey, visited the region in 1908, and says: "The results of structural studies in the Cracker Creek district indicate that the 'mother lode' is not notably displaced by transverse faults. Within the vein itself, however, there are faults which affect the orebodies. Some of the smaller veins have been offset by faulting. The fact that the faults of known attitude are normal, and that in the movement upon them the horizontal component is commonly as important as the vertical one, should be taken into account in the development of such orebodies as have been displaced."

Fushun coal is invading the Korean markets. The State railways have decided to use it, and the Kyushu coal mines are already feeling the effect of the competition.

PLACERS OF TIERRA DEL FUEGO.

Written for the MINING AND SCIENTIFIC PRESS
By S. H. LORAM.

Reading the article 'Gold Region of the Strait of Magellan', by R. A. F. Penrose, Jr., in the MINING AND SCIENTIFIC PRESS of January 23, 1909, I was struck by the difference in his general impressions from those formed by myself during a visit to the region from November 1905 to January 1906. As very little has been written on the subject, my own story may yield further enlightenment.

The southern and western portion of the region I do not know, but those interested will find useful data in 'Geological Observations in South America', by Charles Darwin. The northern and western part of the island is covered with the same formation which stretches over the greater part of eastern Argentina, the bulk of Patagonia, and large portions of southern Chile. The deposit is stratified and strikes parallel to the axis of the Cordillera, with a slight dip from the range on either side. It consists of mudstone, clay, sandstone, gravel, and limestone, with all sorts of gradations of one into the other. In color it is a pale slate-gray, weathering on the cliff faces to yellowish white. The texture is soft, as may be imagined from its composition. Though current-bedding is common, this enormous mass of material shows no bending or faulting, as far as I am aware, south of Lat. 42. Just north of this point the first fault shows up, on the extreme north end of the island of Chiloe. The southern portion shows what Darwin termed the 'boulder formation', consisting of scattered ice-carried boulders, often to be found lying on the surface, and particularly noticeable in Tierra del Fuego on the low-lying stretch of ground between San Sebastián and Useless bays. The reference of the deposit to the late Miocene by Julio Duplaquet* is, I believe, correct. His elaborate work was done in south Chile. The formation rests in places on diorite, and in others on older sedimentaries. According to Darwin, in Tierra del Fuego it lies on early Cretaceous slate. Raised beaches, formed by shore denudation in periods of comparative rest during the present elevation, are visible at several places. I noticed the three low terraces, and it is probable that the remains of as many more would be found by careful search. The total thickness of the deposit I do not know, but there is direct evidence of its being over 1000 ft. thick at Carelmarpú, Province of Llanquahué, Chile, and it may be even double this. In Tierra del Fuego the surface is rolling country, cut through by sea-worn valleys and straits, and terminating on the east coast in what is really a vertical section along that particular line, with some cliffs 50 to 60 m. high. Judging by the pebbles, the deposit was derived from the denudation of hornblende-quartz-schist, diorite, syenite, andesite, clay-slate, and some dark eurites. The first three of these are well known, as the country rocks contain gold-bearing lodes, besides carrying small

quantities of the precious metal themselves; consequently the deposits from them might be expected also to contain gold, even if in minute quantities, as in the present case. Once above sea-level, denudation started on the accumulated soft beds by wave-action; wide bays, inlets, and channels were cut, the lighter particles being carried away, while the gravel and heavier constituents, as oxide of iron, garnet, gold, and the like, remained behind in concentrated form. It must be remembered that this action came into play successively on all parts of the surface as they emerged from the sea (in other words, it has all been sea-beach once), although naturally more intensified at places that were sea-shore during the periods of comparative rest, than where the land passed through the surf-line while undergoing rapid elevation. This concentration would be increased at the same time, and continued up to date by fresh water in the form of rain and rivers on the land beyond the reach of the sea.

Especially with reference to the east coast, the Atlantic is rapidly eating away the land, and the swift north-bound current is stained muddy with sediment for as much as 200 yd. out from the shore. The prevailing wind is from the west, or 'off-shore', but there are occasional furious gales from the south-east during winter, and if one of these coincides with the high spring tide (the rise and fall of which is 40 ft.), allowing the force of the heavy sea to strike full on the base of the vertical cliffs, a whole metre of the entire coast will disappear in a few hours. The shock of the waves, even in summer, may be felt a quarter of a mile from the shore, and resembles the tremble of a slight earthquake. From actual measurement at the Páramo, at least 90 ft. of the shore had been removed during the 18 years previous to my visit. When this action is applied to a hill-side, or across the mouth of a valley, at the surface of which there has already been a first concentration, a second takes place, and in this way it appears that the richer deposits of the island have been formed. There are cases, however, where one or the other concentration alone has been sufficient to produce gold deposits of economic value. To the double process belong the beach deposits of Páramo and Cullen; to a single concentration may be referred some comparatively poor ground, accessible at low tide, at the base of the cliffs forming Nombre Head; while to the estuary-formed deposits, partly aided by fresh water, belong the inland grounds of the Rio del Oro, Rio Progreso, Rio Verde, and so forth.

It seems improbable that the Ona Indians, who inhabited the northern part of the island, knew or made use of the gold. They were a well built powerful race, who lived wandering hunting lives, existing chiefly on the guanaco, which served for food and clothing. They were entirely in the chipped-stone age; of the metals apparently they had no knowledge. According to the 'Estadística Minera de Chile', the gold was first brought to public notice by Serano Montaner, an officer in the Chilean navy, who visited the island in 1880; in the same year work was started on a tributary of the Rio del Oro, and also on the Rio Santa Maria, while some years later came the discovery of the Páramo and other east-

*'Estudio de la Zona Carbonífera de Chile', Boletín de la Inspección de Geografía y Minas. Dirección General de Obras Públicas, Chile.

coast deposits, and in '87 those of the southern islands of Lennox, Navarino, and so forth.

With regard to the east and south-coast Argentine deposits, they were first worked by Julio Popper, who seems to have been a remarkable character, combining talent, administrative ability, resource, and courage, with a want of scruple to an extraordinary degree; even when compared with the somewhat curious collection to be found among the vanguard of pioneers he was unique in his unscrupulousness. A Rumanian by birth, after a varied career in Europe, during part of which time he was in the Russian army, he went to the Argentine, and in Buenos Ayres started a company which, under his direction, began operations at the Páramo. Communication with the outside world was by schooner to Buenos Ayres, 1300 miles away; or three days journey overland through an Indian-infested country to Porvenir, and across the Strait of Magellan to Sandy Point. At the latter place Popper's imperialistic tendencies had made things even more dangerous for him than among the Indians. The miners formed a sort of half-military garrison. They received their pay in five or ten gram gold pieces made on the property, bearing the inscription 'Julio Popper. Tierra del Fuego', on one side, with the crossed picks and the weight on the other. These coins are worth today anything up to ten times their intrinsic value as curiosities. Postage stamps of similar type also were issued. A paper read by Popper before the Geographical Society of Buenos Ayres, giving a description of the island and its inhabitants, showed the work of a keen scientific observer. Popper came to a sudden end in Buenos Ayres, and it is current belief that he was poisoned in revenge by one of a party of prospectors whom he had disarmed and turned adrift from the Páramo to find their way as best they could to Sandy Point.

The beach worked at Páramo was of the double-concentration type, as already described, and from the accounts of those who were there at the time, in its virgin state it must have been wonderfully rich. The gold is found in a strip 11 km. long by about 25 m. wide, extending up the beach from a few metres above ordinary high-water mark. Usually there is a covering of quite poor sand about 50 cm. thick, under which comes a layer of 'black sand' about 5 mm. thick, which carries the gold; lower again is more sand and gravel, and then the mud-stone bedrock, usually about 1.75 m. below the surface; occasionally there are two layers of 'black sand', but the surface of the bedrock is poor in gold. The black sand is both variable and patchy in itself and its gold content. The first attempt at extraction was made by sending the rich streak by portable railway to a central works, where a small steam-plant, with pumps and other machinery, was erected. The gold being fine and laminated, was not satisfactorily saved on ordinary plates, and after several attempts the idea of central working was given up. A number of small portable plants were then constructed, to work the rich patches where they occurred on the beach. This process is in use up to date. The machines consist of a series of four corrugated amalgamated plates, about 14 in. wide by 16 in. long, placed zig-

zag one above the other at about a 35° slope. Over them is a wide shallow box-reservoir filled with water, and a small platform on which the sand is shoveled, to be sluiced through a 1/4-in. grizzly and over the plates by a small stream of water issuing from a hole in the reservoir. Another shallow box serves as a sump, from which the wash is lifted by a bucket to the upper box to serve over again; while the tailing is shoveled out from time to time. The equivalent of the lost water is brought from the sea in a barrel fitted with a spreader and pulled (rolling over and over on itself) up the beach by a horse. The outfit requires three men—one bringing water, one shoveling sand, and one lifting water from the sump. The capacity is about three cubic metres per ten hours, and although the labor is excessive, the amalgamation is remarkably good. Repeated and careful panning of the tailing shows mere traces of amalgam. The plates are not silvered, but after dressing are kept under a current of sea-water, and remain perfectly bright; although they tarnish immediately if used with fresh water, more particularly on account of the general peaty content of the ground. For shifting from one spot to another along the beach, the whole plant is mounted on a light sledge, and can be drawn by the water horse. Usually several days are spent in stripping the poor sand and collecting the rich streak into heaps, which are washed when sufficient has been accumulated.

About 18 years ago sheep-ranching was started by some farmers from the Falkland islands, and soon afterward by New Zealanders. Whether it was preference, or the fact that sheep were easier to hunt than guanaco, I do not know, but the Onas cultivated a liking for the former, which led to trouble, and the otherwise gentle shepherds drove the Indians (those that were left) from the grass-land of the North down to the southern forests and swamp, where a few still exist, being supposed to be perfectly tame. After the Indians were driven out, business prospered, and the island today supports about a million sheep, which form the main industry of the region.

On the inland raised beaches, particularly where further concentrated by streams, mining by hand-labor and washing in 'long toms' seems to have been carried on without great fluctuation by numerous small parties of hard-working Austrian miners, with fair success, compared to their modest requirements. Data as to the number of men or the output are wanting, but the 'Estadística Minera de Chile' estimates the production of the whole region during 1903 and 1904 at 137 and 170 kg. fine gold, respectively; practically the whole of which would be from small workings.

About 1900, some of the sheep ranchers had the ground examined by a New Zealand expert, with a view to investing capital, but after experiments extending over a season, the conclusion arrived at was unfavorable, and things lapsed into their usual routine until 1902-03, when the Compañía Sutphen de Lavaderos de Oro was formed in Buenos Ayres, with 750,000 Argentine pesos* capital; some 140 claims

*The Argentine peso is worth about 45 cents.

were taken up, and a small open-line bucket-dredge was purchased, which, after £30,000 expenditure and two years work, was finally ready to run on the Rio del Oro. Unfortunately, changes in administration were the cause of alterations in design. I believe that the pilot-house, originally placed on the main deck, was shifted to the roof by a second manager, and replaced in its original position by a third. Moreover, the dredge was built on the understanding that it was to handle small gravel only, such as existed on the surface, and was not provided with grizzlies or trommel. Operations showed up quite a fine collection of Darwin's boulders, of various sizes, up to those big enough to bring the digging engine from full speed to a dead stop when a bucket got underneath. In addition to this, the clay bottom was of such consistence that the buckets frequently went down as full as they came up. Under these conditions, as may be imagined, break-downs and stoppages were not infrequent. Gold was found and recovered, but when it is remembered that coal cost at least \$35 U. S. gold per ton, and that the cost of labor and other supplies was in proportion, and that the season, although variable from year to year, on an average runs from November to May, I think I am safe in stating that the precious metal was not extracted at a profit, or in quantities which would lead one to suppose that it ever would be. The capital of the company was increased and four large dredges were ordered from Holland. One was erected, and made a short run just before the end of last season. Results were stated to be satisfactory, and as the dredge began on a known favorable spot this is very likely the case. Meanwhile the 'gold fever' had spread. Land was taken up all over the island and the surrounding region; reports stating the millions of cubic metres dredgeable and the gold content (usually 1 to 3 and sometimes 5 gm. per metre, or 0.074 to 0.125 oz. per cubic yard) were issued, often when not more than two or three persons had ever visited the spot, and such as did had gone away again after a few days' stay. Further delay would probably not have improved matters, as, excepting the Austrian guides, few of the 'experts' were sure of gold when they saw it. One company, in the most accessible part of the island, began work on the basis of two bore-holes, one at either end of the property. The majority of the companies did not go to even that trouble until after the capital was subscribed and the machinery on the way. Many of the companies' shares were at a premium, some as much as 50%, before there was more than a tent on the ground; and then some of the wily promoters sold out. Another curious feature was that gold as dust and nuggets was at a premium also. The current price in the region at the time of my visit was three Chilean pesos* per gram (or \$26.13 per ounce), while its value anywhere else would only have been about 1.80 pesos. We have seen a good deal written of late with reference to gold production and expanding industry, so that some may be inclined to attribute various reasons to this particular instance, but I am personally of the impression that it was a case of supply and demand, the latter being for exhibi-

tion purposes and 'salting'. Generally the showing of dust supposed to have come from a property, and a certified list of claims somewhere, backed by the statements of an 'engineer' (who received the bulk of his pay in fully-paid shares of the company, if formed) were sufficient to find all the capital called for. The following is an incomplete list of the companies formed, with the amount of capital of each. Shares in the majority of these were at one time quoted at a premium. To this must be added a considerable amount of private capital spent both on grounds and inspection; plus those less fortunate concerns that did not get organized and quoted in time for the boom.

LIST OF PRINCIPAL COMPANIES FORMED TO WORK GOLD IN MAGEL-LAN TERRITORY, 1903-1906.

*Argentine pesos.
†Chilean pesos.

Of the above list, as far as I am aware, the only two companies carrying on active operations today are the Sutphen* and Lennox, with what results I do not know. Of the rest it is difficult to get particulars, their shares are no longer quoted on the stock lists, and even the shining brass plates that indicated their official headquarters have lost their brilliance, or have gone altogether. Three, the Rio del Oro, Rio Verde, and Rio Progreso, which were formed, floated, and managed by John D. Roberts, liquidated in June last. The first two lost all of their capital, and had some small outstanding debts. The third was more fortunate, and is now returning to its shareholders 33d. for each £1 share surrendered. According to a statement issued by the shareholders called to liquidate the company on April 25, 1908, the dredge started work on November 11, 1907, and until its final stop on March 14, 1908, had run 80 days and been stopped 44; during this time it had produced 8988 gm. gold (not stated fine or otherwise), corresponding to 112 gm. per day working time, or 72 gm. per day total time. The secretary of the company stated that he believed the capacity of the dredge to be one thousand cubic metres per day, so that the production would work out at 9.112

*The Chilean peso at that time was worth about 28 cents. *Sutphen \$10 shares are quoted at \$2 nominal.

gm. per cubic metre. The manager, Mr. Roberts (who was not present at the meeting), sent to say that he believed when once the dredge reached the actual bed of the Rio Progreso, where the dredgeable ground was much narrower, results should considerably improve. The other two companies had not even that amount of data to offer, but if their financial state was a guide to the results obtained, the recovery must have been somewhat less. John D. Roberts, the once well-driller, then dredge expert, and transitory gold king of Sandy Point, will long be remembered for his successful methods of extracting the yellow metal, even if he has not materially increased the world's supply. There are others. Beach-washing continues as it has for a number of years, being the winter resort of the Austrians who shear sheep during the summer and work with an energy worthy of better remuneration during the winter, principally sustained by the hope that a favorable storm will leave good concentrations on the beach at a depth that can be worked, and allow them to compensate by a well-earned 'good time' in Sandy Point for the long hours of standing in freezing sea-water. In summer a few men are induced to remain on the claims to keep possession, as is required by Argentine law.

At the time of my visit to the Páramo, December 1905 (midsummer), some half-dozen men at work managed to make on the average 70 pesos, Chilean money, each per month from the thin seam and black sand, which by choosing the better patches, gave from 1 to 3 gm. per cubic metre. The following is from a report made just before leaving the region in January 1906: "With reference to Tierra del Fuego as a whole, I am strongly of the opinion that if any payable properties do exist, they do not form 10% of the number in course of formation into companies; while the rest are simply 'wild-cat' schemes from start to finish." In the light of further experience I undoubtedly exaggerate. Grounds amenable to profitable work in a large economical way may exist, but proof up to date is wanting.

TECHNICAL KNOWLEDGE OF MINING.

*There is at the present time a general desire among miners to acquaint themselves with every phase of their industry, including the technical part of it, and there are numerous schools for gratifying the desire at reasonable cost. There are a thousand and one things about a coal mine which it is desirable that all coal miners should know, and which form an interesting study. In these days of explosions and accidents in mines, by which scores of miners are hurled into eternity without warning, it is important that every man who goes into the mine should know the dangers of his calling, and it affords pleasure to know that so many young men are spending their time in acquiring a technical knowledge of the danger, in addition to their practical knowledge. They thus become better able to take care of themselves, and in addition qualified for holding any position about the mine.

A coal miner who does not think and never changes

his work in the mine can work all his life at the face and know nothing about coal mining, except knocking down coal and loading it into the pit-cars. The man who has a desire to know all the details of mine operation, who has worked at every kind of employment, and who has used the text-books on mining, has generally got far ahead of the man who started at the coal face and never did anything else. The latter knows that there is such a thing as gas, and knows it has exploded and will explode again, but is not able to explain the reason. The former knows it is there, knows how it is produced and what are its chemical properties, and under what conditions it is most dangerous. He knows that a sufficient quantity of air will render it harmless, and he knows how to conduct the air to the face of the workings to carry it off. The miner who has not made a study of these things cannot conduct the air to the face. Many of them are strangers to overcasts, regulators, water-gauges, and anemometers. They may have heard of them, but so far as actual experience with them, or their uses, is concerned, they have had none. The same is true of the safety lamp. In a good many cases men have worked for years in a mine and are as ignorant as a child about its uses.

If one were to tell many of the coal miners that marsh gas in its pure state is not explosive, they would think him an ignoramus. If he told them the explosion caused by a mixture of air at, say, 5 cu. ft. of air to 1 of gas would not be as violent as it would if 8 or 10 cu. ft. of air were used, they would reason that air never exploded, and to increase its quantity in a mixture would decrease the force of the explosion. If told that the explosion would be most violent at 9½ cu. ft. of air to 1 of gas, and that it would cease to be explosive if there was present about 14 cu. ft. of air for 1 of gas, they would in all probability think the one making the statement had taken leave of his senses. If told that it would require 16 hp. to put 20,000 cu. ft. of air through an airway, but that 2 hp. had put 10,000 ft. through, they would reason that one horse could do as much work as another, and if 2 could put 10,000 cu. ft. of air through an airway, 4 ought to be able to put 20,000 through the same airway, and it would be hard to convince them to the contrary.

If told that a single pound of powder had a force that would move or propel 480 foot-tons a space of one foot in a minute, they would look at that big pile of rock, or coal, or whatever it might be, and then look at the mite of powder, and say "impossible; it can never do it."

Strength of sand-cement mortar decreases with the percentage of voids in the sand. For this reason the less perfectly sorted bank sands are to be preferred to river sand. The average tensile strength at the end of 180 days of mortar made from 8 river sands was found in the Structural Materials Testing Laboratory at Forest Park, St. Louis, to be 438 lb. The corresponding figure for 14 bank sands was 611.

Java has an important gold output. For February the Ketahoen mine produced 1950 oz. of gold and 2646 oz. of silver.

*Abstract from United Mine Workers Journal.

THE STORY OF BINGHAM CANYON.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. MACFARREN.

In 1862 Gen. P. E. Connor, in command of the Third California Infantry (volunteers) was ordered to Utah, as it was thought necessary to keep a force of Federal troops there. Johnson's army of 6000 or 8000 men that had been stationed at Camp Floyd since 1858 had been withdrawn some time previously to take part in the Civil War. Gen. Connor arrived with his troops in the Salt Lake valley in October 1862, and was met by orders from Brigham Young, head of the Mormon Church, not to cross the river Jordan. Gen. Connor answered in a characteristic Western way that "He would cross the Jordan, though all Hell yawned beneath it." And on the following day marched his troops—a handful as compared with the opposition that could have been brought against him—with fixed bayonets and loaded rifles through the streets of Salt Lake to a point overlooking the city, now known as Camp Douglas. The Third California Infantry had been recruited from patriotic miners and prospectors who were anxious to proceed to the East and take part in the great Civil War, then going on. Gen. Connor, with the idea of lessening the discontent of his men, and believing that the solution of the Mormon question lay in a large influx of people of other sects and creeds, encouraged and assisted his soldiers to prospect the surrounding country by sending them off on trips, ostensibly to look for Indians. This resulted in the discovery and slow development of mineral at several different points. By reason of this initiative and his subsequent activity in mining, Gen. Connor deserves to be styled the father of mining in Utah. It had been known in a general way that mineral existed in the country, but the Church discouraged all attempts at prospecting, believing that the energies of its people should be applied to tilling the soil, and fearing the increased strength of the Gentiles that would result from mineral discoveries.

Bingham canyon lies in the Oquirrh range of mountains, 20 miles across the valley and southwest from Salt Lake. These mountains rise precipitously with narrow canyons, from the altitude of the plain, 4000 or 5000 to an extreme height of 10,000 ft. In the early days the canyon was a wilderness, little known, and heavily forested with timber of large diameter. In 1863 a party of Gen. Connor's soldiers discovered silver-lead ore in the canyon, and on September 17, 1863, the first formal mining location made in Utah was made on a lode of silver-lead ore. In the following year placer gold was discovered, and in 1865 placer mining became active, culminating in the

years 1868 to 1872. The total yield is recorded as \$1,500,000. Bingham canyon is the only district in the State in which placer mining has been carried on to any extent. The development of the lodes was slow, because of the prohibitive cost of supplies and the opposition of the Mormons. The Central and Union Pacific railroads were completed May 10, 1869, and a branch road to Salt Lake seven months later. With the advent of the railroad and cheap supplies, lode mining began in earnest. The first earload of ore was hauled 50 miles to Uintah on the Union Pacific and shipped to Baltimore in June 1868. In 1871

The Oquirrh Mountains, Bingham, Utah.

two smelters were built for the reduction of carbonate silver-lead ore; one of these proved successful and encouraged the building of other small smelters. In 1873 the railroad entered Bingham Canyon. About 1874 the surface carbonate ore began to give out in many of the mines, necessitating a change in the methods of smelting to handle the galena. The mining of argentiferous lead ore was actively carried on until the fall in the price of silver and lead; since then it has been of minor importance.

With the passing of the placer period, attention was directed toward working the veins or deposits of gold ore. The first stamp-mill was erected in 1877; this was followed by seven or eight mills of five to twenty stamps, or with Huntingtons, built at various

times, up to 1896. Most of these mills were not operated extensively, as it was found impossible to make a close saving of the gold by amalgamation. The workings were by shallow tunnels, not exceeding a few hundred feet in depth. As depth was attained the gold content of the ore decreased, and with the appearance of sulphide ore, it was necessary to cease mining. Subsequent developments proved that they were working in the 'weathered zone' of a copper deposit, and practically all of these one-time gold mines eventually became copper producers. With a view to making a higher saving of the gold, a dry-crushing mill and cyanide plant were erected on the Highland Boy mine, but the operations were unsatisfactory because of the large amount of copper in the ore. Utter failure stared in the face Samuel Newhouse, the head of the enterprise, and his associates, until they learned that they were just passing through the surface shell into what has been and probably still is the greatest copper mine between Butte and Bisbee. In 1896 and 1897, 5000 tons of sulphide copper ore were shipped from the property. Copper mining at Bingham may be said to date from this time, for although copper ore had been shipped before, and it was known that large bodies of sulphide ore existed, its value or possibilities had not been fully realized. In 1896 the Utah Consolidated Mining Co. was organized to take over the Highland Boy and other properties. In 1899 the company put into commission a modern 250-ton smelter of roasters, reverberatories, and converters; this was soon increased to 750 tons daily capacity. The smelter was placed in the Salt Lake valley 15 miles from Bingham Canyon. Part of the remarkable success of this property has been due to the self-fluxing nature of the ore, being mainly silica, iron, and sulphur, in approximately equal proportions. The period immediately following 1896 was marked by the formation of large companies, the development of immense bodies of sulphide ore, and the erection of modern smelters of large capacity.

The sedimentary rocks of the Bingham district are quartzite, metamorphosed limestone, and some calcareous shale. These have suffered intense fissuring and intrusion, and some faulting. The orebodies are localized in the part that has undergone the greatest disturbance. The intruding rock is monzonite porphyry occurring as dikes, sills, and laccolites. The mineralization of the district is intimately connected with these intrusions. Flows of andesite have buried part of the district, but have not induced mineralization. The ore occurs: (1) as replacement deposits of copper ore in limestone; (2) as silver-lead ore with some copper and gold in fissures; and (3) as copper minerals disseminated throughout the monzonite. The ore occurring in the less soluble quartzite is lean, and in narrow bodies mainly confined to fissures. The copper content of the sulphide ore—that from the deposits in limestone—is from 2 to 5%, and of the workable monzonite porphyry $1\frac{1}{4}$ to 2%. The amount of the gold and silver additional varies, but is always an item of importance. Most of the sulphide ore is smelted directly, but that in the porphyry requires concentration on account of its low tenor. It is considered that the original magma of

the porphyry contained mineral and that the surface portion of this porphyry to a depth of some 300 feet has been further enriched by mineralizing solutions and secondary enrichment to an extent to make it commercial ore. This enriched ore appears to conform to the configuration of the surface and to extend to a fairly constant depth.

For ten years previous to 1896, E. A. Wall had been cognizant of the possibilities of these porphyry deposits and had been quietly acquiring them. In 1899 the first porphyry ore was milled, both as a commercial enterprise and as an experiment. Following this a few small mills were built and some old ones utilized to test the porphyry on a commercial scale. In 1903 the Utah Copper Co. was organized. In 1904 it put into commission in the lower part of the canyon an 800-ton concentrating mill running on porphyry ore mined by the caving system. This was the first actual demonstration that the porphyry could be made a paying proposition by operating on a large scale. Guided by the results and experience of this mill, a second and more elaborate plant was erected at Garfield, 18 miles from the mines; this plant has a capacity of 6000 tons per day, and has now been in commission two years. The ore is mined by stripping the deposit of its overburden of low-grade rock and debris, and then benching and steam-shoveling the exposed ore.

While the problem of cheap mining has been met by the use of the caving system for underground operations, and benching and steam-shoveling for surface work, and that of cheap milling by the erection of mills of immense capacity, there is still the problem of getting a high extraction. The extraction in milling the porphyry is now from 65 to 70% of the copper content; the concentration on a basis of 20 into 1. One cause for the low saving is the abnormal tendency of the sulphide to slime, another is that part of the value is in an oxidized or reduced state not amenable to concentration, and a third cause is the necessity of fine crushing to liberate the sulphide. Adjoining the 600-ton wet-roll process plant of the Utah Copper Co. is the 3000-ton stamp-mill of the Boston Consolidated Co. Near the mouth of the canyon is the 1000-ton smelter of the Yampa company. At Bingham Junction is the 1000-ton copper smelter (custom) of the U. S. S., R. & M. Co.; at Garfield is the new 2000-ton custom copper smelter of the A. S. & R. Co., both handling mainly Bingham ore and concentrate. At Lark the 3000-ton mill of the Ohio Copper Co. is nearing completion. At Pine canyon, near Tooele, the International S. & R. Co. is grading for a custom smelter that will have the ore of the Highland Boy mine as its main supply. Apparently the story of Bingham canyon as a factor in the mining industry has just begun.

Manganese steel will generally show a tensile strength between 135,000 and 140,000 lb., elongation between 30 and 40%, and an elastic limit between 60,000 and 70,000 lb. In many instances, however, steel of ordinary composition shows an elastic limit of about 75,000 lb., and in a few cases where chromium and other elements have been added, the elastic limit has been as high as 85,000 lb.

MINERAL RESOURCES OF VIRGINIA. By Thomas Leonard Watson. Published under authority of the Virginia Jamestown Exposition Commission, Lynchburg, Virginia.

This handsome volume of 650 pages was prepared to render available the scattered information upon the economic geology of the State of Virginia. The Eastern mines are less spectacular than the Western, but the mineral resources represent known deposits which furnish a basis for investment on an enormous scale. Virginia has long been one of the great producers of mineral wealth; her annual output is approximately \$20,000,000. The non-metallic minerals constitute the bulk of the production, as almost inevitably occurs in any well populated region, where the demand is heavy for clays, lime, sand, and stone; but Virginia is also a famous producer of metals. The Bertha zinc mines constitute a classic locality, where the ores follow the breccia zones of intense folding and faulting in Cambro-Ordovician limestones. From the early days iron has been smelted, and the industry has grown until there are now 26 furnaces in blast, of which 4 are making charcoal-iron, the total product being about 485,000 tons of pig-iron per annum. It is interesting to note that two electric iron furnaces are also in operation by the Willson Aluminum Co. While the iron deposits are widely scattered, the principal centres of operation at present are in Wythe and Pulaski counties, and in Roanoke and Alleghany counties, farther north. The iron deposits occur along the entire length of the Blue Ridge, and are found scattered through the more easterly counties in the Oriskany horizon chiefly, which also yields the bulk of the Alleghany ores. The mining methods employed are in some instances of great interest; in addition to the steam-shovel, hydraulic mining of hematite and limonite is practiced at the Rich Hill and other mines in Wythe county; and a simple and inexpensive method, known as 'milling' has been introduced in the New River-Cripple Creek area. The latter consists in driving a gangway into the deposit to a suitable distance, where connection is made with the surface. The shaft then constitutes a loading-bin, into which the ore is broken down in a constantly widening funnel. Caving by top-slicing is also utilized successfully on inclined deposits of the Oriskany ores, the Oriskany sandstone and overlying Devonian shale closing in above, and exposing the mine to a minimum risk of collapse. These methods are fully described and illustrated in the text of this valuable treatise. Virginia enjoys the distinction of producing the best steam coal in America. This comes from the Pocahontas, or Flat-Top field, which area embraces most of Tazewell and Buchanan counties in that State, and McDowell, Wyoming, and Mercer counties in West Virginia. The first mine was opened in 1882 at Pocahontas, in Tazewell county, thus giving its name to the entire district. The output is a 'dry' coal, containing about 20% of volatile hydrocarbons; it burns with a smokeless flame, and yet it makes a superior coke in by-product ovens. Another famous coal-area is known as Big Stone Gap, embracing Wise, Lee, and Scott counties, and extending into Kentucky. The coal mined in the State now exceeds 4,275,000 tons per year. Fully half of this is converted into coke, the remarkable yield of 68% of the original weight of the coal being obtained. The discussion of the copper deposits of Virginia is of great interest, in spite of the want of success that has attended the efforts to establish a copper industry. The ores have been erratic, rich masses being sometimes disclosed, as at the High Hill mine in the Virgilina district, in Halifax county, from which 15% ore at times has been shipped, containing in addition 8 oz. silver and a quarter of an ounce in gold. An extensive equipment was installed, but the property has failed to prove profitable. Similar want of success has attended the operations on the 'Gossan Lead', in Floyd, Carroll, and Grayson counties. The prospects are enticing, but the veins and their mineralization are unreliable. Gold mines in Virginia have also attracted attention for a century, the gross output having considerably exceeded \$3,000,000. The story of these mines is well

set forth by Mr. Watson. The interest in them is perennial, and even now a Philadelphia syndicate is investigating certain of these properties in the hope of founding a permanent gold-mining industry. Other deposits to which importance attaches are manganese, pyrite, ochre, rutile, phosphates, barite, and gypsum. The volume is one of great interest, and should attract attention to the advantages of this State, which is only in the infancy of its mineral development.

MINERAL RESOURCES OF ALASKA. REPORT OF PROGRESS OF INVESTIGATIONS IN 1908. By Alfred H. Brooks and others. U. S. Geol. Survey, Bull. 379, pp. 418, Ill. Washington, 1909.

The summary of the mining industry for 1908 shows a decline as compared with the previous year. Mr. Brooks explains this as due to the financial panic and to certain conditions that can be remedied. Lack of water owing to the drought reduced the output of placer gold nearly a million dollars. The total value of the mineral production for the year is placed at \$19,929,900, of which more than \$19,000,000 was in gold. The estimated value of the copper output was \$666,600. The value of the silver was \$74,200; coal, \$19,000; marble, gypsum, and mineral water, \$70,000. The production of lode gold increased about 22%. Mr. Brooks says that the high cost of transportation places so heavy a tax on the mining industry that it is almost impossible in most places to exploit any but the richest deposits. The paper includes a general discussion of mining conditions, costs, and methods, and the mineral land laws. The low status of coal mining in Alaska is no criterion of the future importance of this industry. Up to the present time coal has been mined for local markets only. The high-grade fuels of the Bering River and Matanuska fields are practically untouched. These fields can ship coal only when railway connection with tide-water has been established.

CONTRIBUTIONS TO ECONOMIC GEOLOGY FOR 1907. PART II. COAL AND LIGNITE. By Marius R. Campbell, Geologist in Charge, U. S. Geol. Survey. Bull. 341, pp. 444, Ill., maps. Washington, 1909.

When the series of bulletins called Contributions to Economic Geology was started in 1902 to supply promptly brief summaries of the results of Federal surveys, a single 450-page volume was sufficient to cover the field, including Alaska. The first bulletin was published within a few months after the close of the year. It soon became necessary to print separately the results of Alaskan surveys, and a few years later the data regarding coal and lignite were segregated and published by themselves. In the meantime the inclusion of illustrations added to the value of the papers, but greatly delayed publication. The great expansion of Survey work in the Western coal fields threw a heavy burden on the geologists, and the final result is the publication of this report, 18 months after the completion of the work. While the value of the reports has been increased, the benefits intended to be derived from the establishment of the series of bulletins is largely lost.

INVESTIGATIONS RELATING TO IRON AND MANGANESE IN 1908. By E. F. Burchard, E. C. Harder, and Sidney Paige. U. S. Geol. Survey, Bull. 380-E, pp. 115. Washington, 1909.

Advance chapter from Contributions to Economic Geology by the United States Geological Survey, with notes on the Clinton iron ores of the South, and the iron ores of Colorado and New Mexico, and the manganese deposits of the United States.

TRANSACTIONS OF THE AMERICAN INSTITUTE OF MINING ENGINEERS, Vol. XXXIX. 8vo., pp. 949, Ill. New York, 1909.

This volume contains, in revised form, the papers and discussions for 1908, with the exception of a few held over for volume forty. The wide range of subjects treated and the high character of the material attest the firm position which the Institute holds in the esteem of mining engineers.

INVESTIGATIONS RELATING TO RARE METALS IN 1908. By Frank L. Hess. U. S. Geol. Survey, Bull. 380-D, pp. 40. Washington, 1909.

Illinois Mineral Output, 1908.

*Includes in 1907: infusorial earth, metallic paint, quartz, sienna, umber, and sand lime brick. In 1908: coke and by-products, pyrite, sand-lime brick, and natural cement.

Coal in New Mexico in 1908.

The total production of coal in New Mexico in 1908 was 2,467,937 short tons, having a spot value of \$3,368,753, according to statistics collected by E. W. Parker, of the United States Geological Survey.

New Mexico did not suffer so much from the panic and business depression of 1908 as did some of the other coal-mining regions. The actual decrease was 161,022 short tons, or 6.12%. The value decreased in somewhat greater proportion—from \$3,832,128 to \$3,368,753, a decline of \$463,375, or 12.09%. The features of the year were the heavy falling off in the demand for coal by the railroads and by the manufacturing and smelting industries, and the considerable increase in the production of coke by the Stag Canyon Fuel Co. of Dawson, Colfax county. This coke is shipped to allied interests in Arizona, and displaces equivalent amounts of Eastern coke in that market.

Oliver Continuous Slime Filters.

Below follow data in regard to the operations, cost, etc., of Oliver filters at Minas del Tajo, Rosario, Sinaloa, Mexico, on a 130-ton slime plant. The equipment is: two Oliver filters of 300 sq. ft. filtering surface each, being 11 ft. 6 in. diam. by 8 ft. wide; two dry vacuum-pumps, 6 by 7 in., at 150 rev. per min.; one duplex compressor, 6 by 6 in., at 160 rev. per min., single-acting; one duplex-plunger wet vacuum-pump, 4 by 6 in., single-acting; one 2-in. centrifugal pump for charging filters; necessary shafting, and fittings for the above, as they are belt-driven; one 20-hp. 220-volt, direct-current motor which shows 55 amperes (about 16 hp.) when filters are working at the rate of 173 tons of dry slime per 24 hr., vacuum-gauge reading 24 in. (26 to 28 in. can be obtained at sea-level by using larger vacuum-pumps). The average for six months of filter-pulp is 3 oz. silver, \$1 gold per ton of slime; discharged pulp 1.2 oz. silver, 18c. gold per ton of slime; filter-pulp 1.22 sp. gr. or 2.3 tons of solution to one ton of dry slime; moisture discharged in slime, 35%; assay of solution saved, 1.3 oz. silver, 0.033 oz. gold, 0.117% KCN, and 0.03% CaO; soluble metal-values in discharged slime, 0.12 oz. silver, trace of gold, and 0.35 lb. KCN per ton of dry slime. These two filters working 18 hours per day treating 130 tons dry slime, make 15 rev. per hour. There is no increase in solution due to the wash-water. The water added is practically equal to the moisture discharged. It is found necessary to clean the cloth every two weeks with hydrochloric acid. This operation takes

from 1½ to 2 hours. It is asserted by users that the power and labor saving is an important feature; that a greater saving of KCN is made than with any other type of filter, while the operation of the filter is absolutely continuous. The costs have not been figured in detail. Before the installation of the filters it was \$1; after the installation of the filters the cost of treating the slime was reduced to 75c. per ton. The cost of operating and maintaining the filters has not been figured exactly, but will not exceed 20c. per ton of dry slime.

Commercial Paragraphs.

E. D. BULLARD, San Francisco, advises that he now has the agency for the 'Milburn Light', which is an acetylene lamp made in all sizes, from a miner's light to those used in open-air construction, around steam-shovels, dredges, and the like.

THE DENVER QUARTZ MILL & CRUSHER Co., Denver, calls attention to an error in the note published on page 36 of our issue of July 3. It was there stated that the largest mill made by that concern is 5 ft. 6 in. diam. This should have been 8 ft. diameter.

THE C. O. BARTLETT & SNOW Co., Cleveland, Ohio, has lately closed contracts with the McGillveary Coal & Coke Co., at Coleman, Alberta, and with the West Canadian Colliers Co., Bellevue, Alberta, for complete coal mine equipments, including steel tipples, power plant, and haulage systems for both companies.

The ALLIS-CHALMERS Co. announces that Edward G. De-wald, formerly manager of the water-wheel department of the Platt Iron Works, Dayton, Ohio, has joined the engineering staff of its hydraulic turbine department. He will make his headquarters at San Francisco, and will devote his special attention to the Pacific Coast business.

The SULLIVAN MACHINERY Co. has opened a branch office at Australasia Chambers, Martin Place, Sydney, New South Wales, to further the sale of its air-compressors, rock and diamond-drills, coal-cutters, in the Australasian commonwealths. Its establishment is due to the growing importance of the mining industry in that field. The new office is in charge of George R. Mair.

It will be of interest to mining men and shippers generally to know that a new line of fast and commodious vessels has been started by Jebson & Ostrander of Seattle, and is now running with the sister ships *Ella* and *Erna*, both of 3500 tons and 14 knots. These boats make regular sailings between Seattle and Corinto, Nicaragua, and intermediate ports. Two more vessels will be added soon to the fleet. The *Ella* has just been overhauled and re-equipped for first-class passenger traffic. The roomy berths have up-to-date fittings, there are fine promenade decks with free chairs, commodious bath-rooms, excellent cuisine, and the courtesy and attention of the officials will be appreciated by all who have to journey to Mexican and Central American coast ports.

Catalogues Received.

THE A. LIETZ Co., San Francisco, announces that its Solar Ephemeris for 1909 is ready for distribution. The usual data required by the surveyor in determining the true meridian by solar or stellar methods is included.

The A. S. CAMERON STEAM PUMP WORKS, New York, has prepared a little booklet for distribution at the Alaska-Yukon-Pacific Exposition. It contains interesting views of some of the buildings as well as of Cameron pumps.

The PACIFIC FOUNDRY Co., San Francisco, has just issued a catalogue on Kilker's Matte Tapping Car. It completely illustrates and describes this ingenious device for handling matte. A novel use of the car is shown, wherein the running gear is replaced by a stationary spindle and the matte launder is arranged so that either of two 'cars' may be filled. The solidified cakes are later dumped directly into a receiving car. If you have not heard of this device, send for a catalogue.

EDITORIAL.

THE HOUSE framed one tariff bill. The Senate framed another. The President is sitting on both and smiling. As he is a large man with much patience, the outcome is inevitable.

LISTED California oil companies paid \$558,610 in dividends in June, and have paid a total of \$24,018,741 up to July 1. This measures but a small part, however, of the local benefits of the discovery of petroleum.

CALIFORNIA produced in 1908 a total of 1,654,000 tons of gold ore, which yielded an average recovery by amalgamation of \$5.71 per ton. In addition, the concentrate produced from this ore, on a ratio of 51 into 1, amounted to 32,000 tons, which had an average value of \$50 per ton.

HEREAFTER mining claims in the National Forests are to be examined on behalf of the Forest Service at the time the survey is made, instead of after application for patent. This change removes a frequent cause of irritation, since under the old rule examination was often so delayed as to require an extra year's assessment work.

CONSERVATION will be an active theme at the Alaska-Yukon Exposition. The first National Conservation Congress will assemble there on August 26. The program as announced includes irrigation, dry farming, forestry, mining, transportation, good roads, pure food, sanitation, and the relation of capital to labor.

MINING experts are just now numerous in the Couer d'Alene region, and lengthy and learned discussions of end-lines and veins constitute the table-talk. It is said the boarding-houses have run short of knives and forks, as knives laid out on the table cloth excellently mark boundary lines, while forks seem to have been designed purposely to represent veins.

RUSSIAN laborers were brought into Nome this year by someone who modestly refuses to reveal his identity. They were met by a crowd with a brass band and used roughly, according to reports. Eventually most of them were arrested as vagrants and deported. The truth seems to be that there is not enough work to go around this season at Nome.

TELEGRAPHIC despatches still lay stress on the political excitement in Mexico. Enthusiasm ran a bit too high at Guadalajara the other day, and the rioters were given a lesson which will tend to greater self-control in future. President Diaz is wise in the method he has adopted for accustoming the people to the exercise of suffrage. Several years

ago, instead of appointing a Governor for Morelos, an election was ordered, which created a good impression throughout the country. Also the revival of the office of vice-president is comparatively recent, and this year opportunity is given for selection by ballot of an incumbent for the ensuing term. At the same time a successor to the late Governor Cañedo of Sinaloa will be chosen by the people, and a lively canvass is in progress between the rival parties, with Señores Diego Redo and José Ferrer in the field. Mexico is being given her advanced course in self-government under control of a good *maestro*. That Wall Street has faith equally in master and pupil is shown by the fact that Mexican National Railway securities, both Government guaranteed and prior lien bonds, have not moved a half-point in price within the last two weeks.

STRENUOUS efforts are now being made to attract the attention of the world to the resources of Peru. Among these is the establishment of a magazine in English, entitled *Peru Today*. The first number, just to hand, is attractive. It owes its existence to the initiative of Señor Augusto B. Leguía, President of the Republic, a man who had distinguished himself as a financier before being called to serve his country. It is interesting to find at the head of affairs one who is not essentially a politician, and to whom the post yields less emolument than he could derive from his normal pursuits. Peru is enjoying the benefit of a sane administration conducted on business principles.

Reclamation Service Rumors.

Disquieting rumors come from Washington to the effect that Mr. F. H. Newell, Director of the Reclamation Service, is to be removed. It seems that Mr. Newell allowed settlers who owned land which would be benefited by the Government works, to pay their water rates in advance by labor, using scrip instead of cash in the transaction. The Attorney-General has decided there is no warrant in law for this. There is no dispute as to it having been a sensible business arrangement, beneficial alike to the settlers and to the Government, and to remove so clean and able an official as Mr. Newell for such an offense would be widely interpreted as meaning that an excuse rather than a cause was wanted. It would confirm the ugly rumors that Mr. R. A. Ballinger, Secretary of the Interior, has started out to reverse the Roosevelt policies regarding the public lands. It need hardly be pointed out that while this interpretation would be natural, it is not necessary. It is well known that under the last administration there was much cutting of corners, or 'smashing red tape', as we all liked then to call it. Evidently Mr. Taft and Mr. Ballinger, being lawyers, are strict constructionists. If, however, this is all there is in the matter, it should be easy to stop any illegal practices and ask Congress for remedial legislation. There is no need to sacrifice an able and honest public official and arouse the suspicion that one of the cleanest public services is to be made the sport of partisan politics and possible graft.

Debris From Oroville Dredges.

Among the open letters this week we publish two communications concerning a meeting of agriculturists to discuss the effect of dredging in adding debris to the Feather and Yuba rivers. The assemblage was called at the solicitation of the mayor of Sacramento. His invitation was explained on the ground of the commercial interest of the city in the agricultural districts said to have sustained injury from dredge-tailing. That the circumstances did not warrant the action seems evident from the extreme disparity of view among those in attendance. The welfare of the agricultural community, with regard to such sources of danger, has been carefully looked after by the California Anti-Débris Association, a protective organization which commands general confidence. The executive committee of the Association has, on numerous occasions, investigated the conditions of dredging at Oroville, and certain abuses were corrected through its instrumentality. The Sacramento convention brought into relief the fact that the recent construction work upon the Western Pacific Railway had unavoidably thrown considerable amounts of material into the streams, which have occasioned temporary difficulties. Captain Thomas H. Jackson, of the Corps of Engineers, U. S. A., at the head of the work of the California Débris Commission, made the assertion that the dredges were not contributing debris to the streams, as shown from the surveys made by the Commission. That the convention realized that the question of possible damage from dredging, as now conducted, was not taken as being serious, was further evinced by the failure of those in attendance to effect a permanent organization. A committee of enquiry was appointed, but the assemblage adjourned *sine die*, so that the committee has no body to which to submit a report. The call of the mayor of Sacramento has performed a useful purpose in reassuring the public concerning the dredging industry. It has thus done much toward removing an ill-founded prejudice.

Rejection of the Yard Mining Claims.

Administration of the public lands on forest reserves develops new phases almost daily. The decision of the First Assistant Secretary of the Interior in the cases of fraudulent location of mining claims by Mr. H. H. Yard and the North California Mining Company in the Plumas National Forest, California, establishes a precedent of great moment. It marks a forward step in the development of bureaucratic functions. It is exalting administrative process to a rank parallel with the legislative. While expressing full sympathy with the Government in its necessary exertions in protection of the resources of the Nation from the grasp of monopolies, we can but regard with apprehension the exercise of authority not distinctly conferred by law.

In the case which has now arisen the Department of the Interior assumes to pass on the validity of a mining claim in advance of application for patent; it annuls the claim when the locator was not seeking to secure permanent possession, when, theoretically, he was himself holding only tentative rights. Al-

though a foreigner may not obtain patent to mineral land in the Territories, the law does not preclude his locating mining claims, which he may hold indefinitely by performing the acts required by statute. The functions of the Department in such matters are amply set forth in the Mining Law, and in advance of the determination of the character of the land, whether mineral or agricultural, no intervention of the Department is contemplated until the claimant proceeds to patent. This is a statement of the situation, quite apart from the merits of the particular case of Mr. Yard and the North California Mining Company. The flagrant abuse of the provisions of the Mining Law which had been made illustrates the need of remedial legislation. It called for Departmental interference in some manner, if a legal way could be found. Once each year, at least, the claimant or his agent is compelled to enter upon mining claims to perform assessment work in order to validate his claims. At such time the Department could obtain an injunction or restrain the claimant on the ground of trespass. This would force the issue into the courts, and not deprive the claimant of any legal rights he might have had, nor lay his claim open to prejudice from fresh locations upon the land. The decision of the Department today that one claim was fraudulently located does not prevent another claimant locating the same ground tomorrow, under affidavit of a discovery of mineral, the validity of which the Department may not call in question without investigation. Until a judicial decision has been reached, the fact of fraudulent location is not legally established, and yet adverse possession, clouding the original title, might thus be invited under the assumption that the act of the Department did restore the land to its original legal status, subject to location whenever a bona fide discovery of mineral might be made. The Departments have been setting an unfortunate example to the people, in expanding their authority in ways for which the statutory warrant seems doubtful. We have felt this to be the case in regard to the withdrawal of coal and phosphate lands from location. The success of democratic government is not to be achieved by usurping power, instead of resorting to the courts. Evidently the Government has hesitated to trust its ability to secure protection of the rights of the people by judicial process. This reveals anew the weakness of the judicial system, overloaded as it is by an absurd procedure which opens the way to placing the stamp of judicial sanction upon iniquity.

Our argument against the method pursued by the Department of the Interior has nothing to do with our opinion of the essential justice of the thing sought to be accomplished. The locations made by Mr. Yard and the North California Mining Company covered 260,000 acres of heavily timbered land in Butte and Plumas counties. Being in a mineral country, the presumption of validity of the claims could not be questioned. The mining company was first organized, and immediately thereafter, as a means for facilitating its operations, the Butte & Plumas Railway was incorporated, being ostensibly no more than a spur line into the mountains from Oroville. But it secured control of Beckwith pass, which was

desired by the Gould system for its projected trans-continental railroad, which has now been built over this route. At the same time the locations made gave the corporation, which was acting thus in the interest of the railways, an apparent control of forests of great value. While these claims lay unpatented the timber could not be touched except for actual use in the mines which might be developed in them, but the case would be different if patent should be obtained. That the persons interested ever intended to proceed to patent is open to question. This reveals another of the tortuous ways of the crafty to gain possession of National resources on favorable terms. The Department of the Interior, being supposedly unadvised of mining claims until application is made for patent, may offer timber rights on the same land for sale to the highest bidder. The bidder, by search of title, finding it clouded by mining claims, may bid at a low figure, assuming the Department cannot give unimpeachable timber rights. The mining and timber claimants will then speedily come to an agreement, and a valid right to cut and remove the timber is obtained at a greatly reduced cost. It is against such abuses that the Department is aiming, and it deserves the cordial aid of all men who have the interest of their country at heart. The region covered by the claims now rejected were shown in the hearing before the local Land Office at Susanville, California, to contain 11,000 acres containing about 160 million board feet of timber, valued at approximately \$320,000. The claims held by Mr. Yard and the North California Mining Company had in the course of nearly five years produced only about \$3 worth of gold. The development of the timber resources of the region have been retarded, as in other cases of similar character on the public lands of the West.

If the method pursued shall be sustained, a bad principle in government will have been become recognized in America. The evils of bureaucratic government are well enough known, and to our thinking the authorities at Washington would do better to utilize the courts, rather than strain after functions which are safe only in the hands of benevolent despots. Who will guarantee that the method created to protect the people may not one day be turned to strip them of right in the interest of a favored few? As a means of facilitating the administration of public lands, preventing many abuses which now exist, it would be most useful to amend the Mining Law by requiring that a locator shall perform the necessary work and make application for patent within a limited period. This would enable the Department of the Interior to legitimately take cognizance of the pretensions of claimants without impugning their rights, as apparently is done by the recent action. This method is followed in other countries, and produces a benefit to individuals and to the general public. At the same time it would appear desirable to grant to individual claimants of title to lands the right to apply for a writ of mandamus in cases where an application had been rejected. It would not be inappropriate to undertake a revision of other features of the Mining Law. It needs mending at many points.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. HAYES is in Mexico.
LOUIS PRATT is at Oroville.
W. C. MENDENHALL has gone to Hawaii.
J. P. HUTCHINS is on his way to Siberia.
S. F. EMMONS has left London for Leipsic.
JAMES A. BARE will be at Seattle next week.
GEORGE OTIS SMITH has been in San Francisco.
HORACE G. NICHOLS leaves August 5 for London.
CHARLES G. YALE has returned from New York.
F. L. BOSQUI is back from an extended visit to Europe.
C. COLCOCK JONES sailed from Seattle July 1 for Alaska.
FORBES RICKARD is in the San Juan district of Colorado.
D. W. BRUNTON has returned to Denver from southern Nevada.
E. R. PEMBROKE has made Salt Lake City his headquarters.
RICHARD PEARCE is spending the summer at Weybridge, in England.
J. H. CURLE has reached London, on his return from Cashmir and Siam.
WILLIS LAWRENCE is superintendent of the Florence mine, Goldfield, Nevada.
R. M. BAGG was in San Francisco, on his way from British Columbia to Los Angeles.
ROWLAND FEILDING returned to London from Italy, and is now on his way to Siberia.
ARTHUR WILKINSON has completed his report on Prestea Block A. mine, in West Africa.
S. J. SPEAK, of Hooper & Speak, has returned to London from West Africa, in excellent health.
R. W. BROCK is confined to the hospital at Ottawa, Canada, on account of diphtheria, but is recovering satisfactorily.
FRED G. MUDGETT has accepted a position with the National Ore Purchasing & Reduction Co., at Rawhide, Nevada.
ALLAN A. DAVIDSON is on the Gold Coast of West Africa, where he is consulting engineer to the Nanwa Gold Mines.
D. R. THOMAS has accepted the position of manager for the Predilecta Mining Co., at Guanacevi, Durango, Mexico.
E. J. CARLYLE, Kyshtimsky Zavod, Russia, was married in London June 4 to Miss C. B. Thomas, of Prescott, Arizona.

HOWARD D. McLEOD has completed a mill for the Midas Galena Mineral Co., on Lake Pend d'Oreille, and is at Sandy Point, Idaho.

C. G. PATTERSON, who has lately been in London, has gone to South Africa, in the interests of the Butters Patent Vacuum Filter Company.

FRED B. REECE, for the past two years with the Homestake Mining Co., Lead, S. D., is now one of the staff of the Socorro Mines, Mogollon, New Mexico.

AUBERT E. BRUCE has resigned his position as assistant to the manager and purchasing agent of the Ray Con. Copper Co., at Kelvin, Arizona, and has taken up his residence in Los Angeles.

HUXLEY ST. J. BROOKS has severed his connection with the Topaz Gold Mining Co., of El Mico, Nicaragua, and is now superintendent of the mill and cyanide works of the Mina Babilonia, La Libertad, Nicaragua.

F. P. GRAVES, of Doe Run, and S. DUFFIELD MITCHELL, of Carthage, have been appointed by Governor Herbert S. Hadley members of the Board of Managers of the Bureau of Geology and Mines of Missouri.

PHILIP WISEMAN, who recently resigned as manager for the Ray Con. Copper Co., at Kelvin, Arizona, is leaving on a trip to San Francisco, Seattle, and the East. His permanent address is 1003 Central building, Los Angeles.

General Mining News.

ALASKA.

KETCHIKAN DISTRICT.

(Special Correspondence).—The It mine is shipping 800 tons of copper-gold ore per month which nets \$20 per ton. There are 200,000 tons of ore blocked out in the mine.—A gravity tram and railroad have been constructed from the Goodroe mine to the harbor at Karta bay. The ore is bornite and chalcopryite carrying from \$2 to \$3 gold per ton on a limestone contact.—The latest discovery in this district is a 3-ft. vein of galena that can be traced for 1000 ft. on the surface. There is some silver associated with the lead.—M. D. Ickes and W. L. Polson are developing a vein of lead-copper-gold ore at Mallard bay. A cross-cut at a depth of 35 ft. cut a 7-ft. vein of good shipping ore.—The Victor Copper Mining Co., operating 12 miles southeast of Ketchikan are driving an 1100-ft. cross-cut adit which is in now 600 ft. Three veins have been intersected. Patrick Heany is in charge of the work.

Ketchikan, July 9.

ARIZONA.

COCHISE COUNTY.

The orebody in which the shaft of the Empire Gold-Copper Mining Co., near Dragoon, is being sunk has widened till at a depth of 80 ft. the bottom is entirely in ore. Seth Merrill is manager.—At the Centurian occasional shipments are being made, but the work is mainly confined to blocking out the ore. A new gasoline hoist has been ordered and will be at the mine in a short time.—At the Copper Chief a heavier hoist is to be installed and the shaft is being re-timbered for a new skip. Frank McGovern is in charge of the work.—The Telfair shaft of the Arizona-Michigan near Johnson is down over 500 ft. in diorite and has cut a small amount of vein matter. A heavier hoist is to be installed and cross-cuts started from the 600-ft. level. Nels A. Nelson is manager.—The Arizona United Mines Co. is opening a body of ore on its Chicora claim that assays 15% copper.—The grading for the smelter at Johnson has been completed and the concrete foundations are being constructed. A gang of carpenters are working on the ore-bins, and many of the smaller mines of the neighborhood are piling their ore on the dumps in anticipation of the blowing in of the furnaces.—The 475-ft. adit on the Virtue property near Paradise cut a vein of 3% copper ore at a point giving 230 ft. of backs.—On the Missouri claim of John A. Duncan samples taken from the lime-porphry contact assayed 20% copper.

GILA COUNTY.

Samples from the vein on the property of George A. Feagles in the Tonto district assayed \$15 gold per ton. The vein is 10 ft. wide and has been sampled the length of the claim.

MARICOPA COUNTY.

The Bisbee Coalition Co. has purchased the properties of the Eureka Mining Co. two miles north of Bisbee for \$200,000. The company will sink to the 200-ft. level and cross-cut from that point.

MOHAVE COUNTY.

Barney McCall has disposed of his interests in the Weaver district to N. C. Pettit and E. B. Van Deman.—The Carter Gold Mines Co. has installed a compressor and is now sinking the shaft with power-drills.—The Union Basin Mining Co. shipped 12 cars of ore from the Golconda mine to the Oklahoma smelters.—James Uncapher is opening a turquoise mine in the Mineral Park district.

PINAL COUNTY.

At a directors' meeting of the Ray Consolidated Copper Co. it was decided to build a mill with a capacity of 5000 tons per day, instead of 3000 as previously planned, and the stockholders will be called to vote upon the issuing of 200,000 shares of stock to raise the money to cover this extra expense.

YAVAPAI COUNTY.

The Business Men's Association of Mayer has taken over

the Rigby reduction plant and will convert a portion of it into a lead smelter. The ores of this district contain considerable lead, which has previously been allowed to go to waste.—The mill of the Independence and Union Hill mines has been repaired and a 10-ton tailing plant installed for the treatment of the accumulated tailing. John S. Jones is manager.—Alex. J. Lyons and E. J. Jordan have taken over the Lulu & Lone Pine property in the Jerome district. Several adits have been driven and a winze sunk that opened some high-grade sulphide ore.—The shaft of the Haynes Copper Co. is down 700 ft., a station cut at the point, and a cross-cut started to the west. The cores from the diamond-drill showed a good copper content at this level.

YUMA COUNTY.

W. G. Read is developing a good prospect on his claims in the Winchester district. Samples taken from several veins cut by the adit assay \$40 gold per ton, with small amounts of lead, copper, and silver.—The Ben Hur group near Vicksburg is held under a \$15,000 bond by J. D. Mitchell and A. Matthews. The property is near the railroad and the owners have a carload of ore on the dump for a trial shipment.—The Planet group at Planet has been purchased by the Lewisohn interests from A. B. Jones.—The Rogers brothers have sold the Brooklyn group of 18 claims to a Los Angeles syndicate.

CALIFORNIA.

INYO COUNTY.

The Keeler smelter shipped 270 tons of lead bullion to the Selby plant during the past week.—From the Cerro Gordo mine 100 tons of \$100 ore were sent over the tramway to Keeler.—A 5-ft. vein has been opened in the Skidoo mine, 14 miles west of Death Valley in the Tucki mountains, that assays \$20 per ton. The five stamps recently added to the mill are dropping on good ore and the monthly clean-up will approximate \$30,000. Matt Hoveck is manager.—E. A. Montgomery, the principal owner of the Cocopah mine, adjoining the Skidoo property, is authority for the statement that a 20-ton mill and cyanide plant will be constructed for the treatment of the company's ore.—The return on a carload of ore shipped from the Shieve & Utank lease in the old Chedago district to the Mammoth smelter at Kennett was \$30 per ton. There are several carloads of similar ore on the dump, and as it is silicious it makes an excellent flux for the Kennett ores.—The Birch creek placers west of Big Pine are now in operation and are washing a 25-ft. bank that averages more than \$20 per cubic yard. C. A. Curl is directing the work.—The Tecopa Consolidated Mines Co. has purchased the equipment and is laying 13 miles of track from Tecopa to the Tecopa mines. The ore is of the lead-silver type and the company has enough blocked out to warrant the spending of \$200,000 to equip a railroad to the mine.

MONO COUNTY.

(Special Correspondence).—The United Gold Corporation has purchased the Sunny Jim group and the Tyler holdings. The company is negotiating for other properties in this district, and expects to commence production on a large scale within a few months. The recently acquired properties are situated a few miles north of the Pittsburg-Liberty group.—The Pittsburg-Liberty is shipping ore running \$200 to \$600 per ton to the smelter, and treating considerable low-grade material at its mill.

Masonic, July 20.

PLACER COUNTY.

J. Pierson, of Colfax, is mining an exceptionally rich bar on the American river, portions of which have run as high as \$1 per pan.—The McGeachin Mining Co., of Sacramento, has purchased the Morning Star mine at Iowa Hill. The property is chiefly valuable for the water-rights owned by the estate.—The Peckham Hill mine is to be re-opened shortly. Earl Tiffnay is the owner.—The El Dorado & Placer Dredging Co. is to build a new dredge at the Cash Rock placer claims. The dredge will be a combination of the suction and bucket types.

PLUMAS COUNTY.

J. Riley has bonded the George Scott quartz mine near

Quincy. The ore is free-milling and some rich pockets have been taken out by the former operators.

SACRAMENTO COUNTY.

The result of the Anti-Dredging Convention was the appointment of a committee of six to investigate the action of the gold-dredges, their effect on the rivers, and the destruction of farming land, and to report such information to the Anti-Débris Association and the California Débris Commission.

SAN BERNARDINO COUNTY.

James H. Hart is running a drift on a 1-ft. vein in the Oro Belle No. 2 that assays more than \$100 per ton.—A raise from the main adit of the Oro lease of the Big Chief Mining Co. cut an ore-shoot that assays \$6000 per ton.—The Oro Belle shaft is down 300 ft. and a station is being cut at that point. The shaft will be sunk another 100 ft. in hopes of striking a sufficient flow of water to supply the mill the company plans to erect on the property.—O. F. Bevere has purchased a one-third interest in the Rambler claim adjoining the Jumbo property.

SHASTA COUNTY.

S. C. Denson, of San Francisco, purchased the Syble mine near French Gulch at auction for \$10,000 in behalf of Charles O. Rose, trustee for the bondholders. The mine was bonded several years ago for \$50,000 and the interest now amounts to \$18,000. No action has been taken as to the future of the mine.—The Bella Vista Oil Co. has been organized at Bella Vista to prospect for oil in that vicinity.—The cross-cut adit on the Yankee John property west of Redding has opened a vein of ore that assays between \$300 and \$500 per ton.—The second furnace of the Balaklala company at Coram has been blown in.

SIERRA COUNTY.

The lower adit at the Tightner mine has broken into the serpentine and is expected to cut the vein at any time. This will give 600 ft. of backs on the Tightner vein.—At the El Dorado the 10-stamp mill is running on a lot of rich ore that was taken out several weeks ago.—Arrangements have been made for the resumption of work at the Sixteen-to-One mine.—The Gibraltar shaft has been unwatered and is being sunk to bedrock.—The main drift on the Gray Eagle opened a shoot of rich ore.—The drift on the lowest level of the Alaska mine has opened an ore-shoot of high-grade rock. This shoot is presumed to be one worked in former days at the mine, which was 1800 ft. long in the upper levels, and excellent milling ore. The present working is 100 ft. below the old works and 650 ft. below the outcrop. George St. John is manager.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Linn Consolidated Mining & Milling Co.'s 50-ton mill is running night and day on a lead-zinc ore, and the net earnings average from \$3500 to \$4000 per month, after deducting mining expenses. A body of medium-grade ore is being followed that is from 5 to 7 ft. wide, the average value being from \$16 to \$18 per ton in silver, lead, and zinc. C. E. Pughe is manager.—A rich find has just been made on the Columbia property situated on Silver mountain. The discovery was made in carrying a stope from the lower adit, the streak being 6 in. wide and assaying 4 oz. gold per ton and 10% copper. The stope is 90 ft. long, with ore the entire length. E. J. Butts, the manager, states that work on a new adit to gain depth will be put under way in a few days, and a compressor and machine-drills will be installed at an early date.—A. D. Bryant, of Silver Plume, has uncovered a 4-in. streak of 400-oz. silver ore on the Seven-Thirty mine, on Sherman mountain. The ground has been opened for 15 ft., with the streak showing the entire length. This ore was found directly under the workings where a production of more than \$100,000 was made a few years ago.—Work on the new adit at the Josephine mine on Kelso mountain is progressing satisfactorily, following a streak of galena that is from 6 to 10 in. wide. J. R. Sapp, the manager, states that a compressor plant will be installed soon.—C. V. Cooper has been appointed manager of the Waldorf Metals Co.,

operating a large amount of ground through the Wilcox adit under lease. Heavy shipments are being sent out over the Argentine Central railroad, from 200 to 250 tons of ore being marketed weekly.—Work has been resumed upon the Walsh group of claims in West Argentine. This property was recently purchased by E. F. Clark, of Minneapolis, and a company is in process of organization. In the shaft that is being sunk on the Walsh vein a streak of heavy lead ore is showing that is from 9 to 17 in. wide and assay tests show the lead content to be 60%, with 45 to 60 oz. in silver per ton.—The Paragon adit on Sherman mountain is being driven steadily forward, two veins having been intersected. The last one passed is heavily mineralized, and as soon as the heading has been advanced for 50 ft., driving will be started east and west on the Walsh vein for the exploitation of the ground. W. F. Cogswell is manager.—A force of men was sent this week to the DeVotie group of claims, situated in the Daily district. The cross-cut is to be driven ahead for the intersecting of the series of veins. Driving is also to be started on the DeVotie vein, as a streak of ore is showing that is from 7 to 10 in. wide. Shipments have brought as high as \$200 per ton in gold and silver.

Georgetown, July 21.

CHAFFEE COUNTY.

After experiencing considerable preliminary difficulty the Kuenzel smelter at Buena Vista has been successfully blown in. The smelter uses oil for fuel and has a smoke-consuming device that is said to give excellent results. Charles A. Kuenzel, the inventor, is preparing to build a number of such plants to work the dumps that are too low grade to ship or mill.

GILPIN COUNTY.

R. S. McConnel and W. McLeod have secured a lease and bond on the London mine in the Twelve Mile district. Sample shipments to the Black Hawk sampling works assayed between \$80 and \$90 per ton.—The Golden Rod mine in Silver creek is being re-opened.—The Fagrellius & Johnson property in Moon gulch has been bonded to Idaho Springs capitalists, who are to erect a mill on the property. A large amount of low-grade ore has been blocked out in the mine.

EL PASO COUNTY.

The plans for a new mill at the Portland Mining Co.'s property at Colorado Springs have been completed and the contracts for the construction awarded. During the building of the mill the quarterly dividends will be reduced 2c. per share. George M. Taylor is superintendent.

LAKE COUNTY.

Operations have been resumed on the Dinero adit at Sugar Loaf mountain. Dudley M. Gray is manager.—The Gold Bug adit has cut a number of small veins from which favorable assays have been obtained.—The Horri-gan brothers are developing the recent find on the Highland Mary claim on Breece hill. The shaft has been in ore of milling grade for the last 25 ft.—Heavier track is to be laid from the Yak tunnel to the Tribune lease on Breece hill and new machinery installed. The ore recently opened on the lease is still of shipping grade. L. R. Johnson is manager.

LA PLATA COUNTY.

A rich discovery has been made on the Old Comfort claim in Root gulch one mile from the Comstock mine. Assays from a 16-in. vein run over \$600 per ton, and float has been found on the property that assayed \$2000. T. J. Crowdis, superintendent of the Tomahawk mine, has purchased a quarter interest in the claim.

SAN JUAN COUNTY.

A shipment of two carloads of high-grade ore was forwarded from the Frank Hough mine to the Durango smelter.—The mill of the International Mining Co., operating the Iron Mask mine, is nearly complete and will be started within the next two weeks. V. H. Yarnall is manager.—J. B. Ross and S. S. Watson have secured a bond on the Little Maud mine in Maggie gulch. Considerable money has been spent in development work and some high-grade ore shipped by former operators.

TELLER COUNTY.

The Zenobia mine on Bull hill is being re-opened by the Zenobia Gold Mining Co., a corporation controlled by Stratton's Cripple Creek Mining & Development Co.—The Clements Leasing Co. has taken over the Gold Sovereign mine and is erecting a new surface plant to replace the one destroyed a short time ago by fire. A 25-ton shipment was made by lessees from the new management.—The La Bella Investment Co. has secured a prospecting permit from the Hart Gold Mining & Leasing Co. on the Jessie G., Fresno, Brooklyn, and Hart claims on the north slope of Bull hill. These claims have not been worked for several years, but in the past a number of high-grade shipments have been made from the property.—The Wild Horse mill has been re-modeled and the stamps are now dropping on ore mined by lessees on that property.—David Mason and John Larson, of Victor, have secured a lease on the Mountain Beauty property above the 550-ft. level.—Three tons of \$100 ore was shipped by the Little Puck Mining Co. from the Climax No. 2 claim on Squaw mountain.—The average return on two shipments of eight tons from the property of the Colorado Mines Investment Co. was \$140 per ton.—The Western Investment Co. shipped a trial lot of its ore from the 650-ft. level of the Rose Nichol mine on Battle mountain.—M. B. Rapp, of Cripple Creek, has secured a 12 months lease on Block 2 in the Dolly Varden mine on Raven hill.—The cross-cut from the 1000-ft. level of the Cresson mine opened a vein that is between 12 and 20 ft. wide. Drifts have been started along and stoping will commence at once. The Cresson company has secured an option on the Moose and Requa properties. Richard Roelofs is superintendent.—A contract has been let to sink the main shaft of the Pinto mine from the 650 to the 750-ft. level.—R. G. Harrison recently shipped the first lot of ore from the Happy Year mine that has been sent out since the mine was shut down several years ago. It is estimated the ore will average \$15 per ton.—The Portland Gold Mining Co. of Victor has commenced grading for the foundations of its new mill between No. 2 and 3 shafts on Battle mountain. Frank M. Kurie is manager.—The Vindicator Consolidated Gold Mining Co. has made another rich discovery. The drifts from the 1400-ft. level opened a 6-ft. vein of smelting ore that assays \$50 per ton. E. J. Trevarrow is superintendent.—Johnson & Hastain shipped four cars of ore for which the average return was \$70 per ton.—The Eclipse No. 1 claim has been purchased by the Jo Dandy Mining Co. from the New Haven Gold Mining Co. J. M. Wright is manager.

IDAHO.

BLAINE COUNTY.

A saw-mill having a capacity of 10,000 ft. per day is being erected on the property of the El Oro Mining Co. on Bear creek, 30 miles northwest of Soldier. The machinery for a mill and hydro-electric plant is being forwarded to the mine, and when these have been completed a cyanide plant will be installed. Joseph Mornington is in charge of the work at the mine.—At the Flick placer mine several miles of ditches have been constructed and new hydraulic equipment installed.—A 25-ton mill and 65-hp. electric motor have been installed at the property of the Bear Creek Mining & Milling Company.

IDAHO COUNTY.

A 4-ft. ore-shoot has been opened by R. L. Wilson on the Wander claim in the Four Mile district.—On the Buckhorn property the 75-ft. adit has opened a 20-ft. vein of milling ore.—The saw-mill built to furnish the lumber for the Elk City and Jennings Dredging companies is now running. A carload of machinery has been shipped for the Jennings dredge and the rest of the equipment will be forwarded shortly. R. H. Bond is in charge of the construction.—J. J. Jacobs, of Marquette, has bonded the Franklin, Comet, and the Gold Brick groups of 23 claims.

KOOTENAI COUNTY.

By over-ruling the Land Office the Department of the Interior has awarded the Yankee mill-site on Big creek in the Coeur d'Alene district to True and Dennis Blake. The Land Office held for cancellation the application of the

Blakes for the mill-site. In reversing the decision, the Commissioner says: "It appears that the mining claims cover a continuing vein or lode, and it is averred by the appellants, and nothing otherwise is disclosed to contradict it, not only that the group is a producing mine from which ore is at present shipped, but that for four or five years past the mill-site has actually been used for mining and milling purposes in connection with the group of claims."

OWYHEE COUNTY.

At a stockholders' meeting of the Potosi Mining Co. a bond issued was voted to raise \$250,000. Eastern capitalists have made arrangements to take the bonds, which are to run for a period of 10 years.—An air-compressor and electric plant have been installed at the Rich Gulch mine near Silver City.

SHOSHONE COUNTY.

A. J. Brainard, manager for the Samson Mining & Development Co., reports a discovery of high-grade galena and carbonate ore in the Bunker-Chance adit on Eagle creek, 5½ miles from Murray. The ore was cut on the foot-wall at a depth of 200 ft. in the lower adit, and a drift on the ore-shoot 50 ft. back from the present find opened a body of concentrating ore 40 ft. wide.—Eight feet of high-grade milling ore was cut on the Black Bear Fraction near Gem. A 2000-ft. cross-cut was driven to intersect the vein, which has since been driven upon for 1000 ft., the face at this time having an approximate depth of 1300 feet.

MICHIGAN.

The Wyandot Copper Co. has cut another vein in the cross-cut west on the third level. The vein is very hard, except for 18 in. on the foot-wall, which was unusually soft, and well impregnated with copper. Two cuts have been taken, but the hanging wall has not been disclosed.—Not more than 18 or 20 men are now employed by the Keweenaw Copper Co. in its mining and exploratory operations. Only a few drills are running underground, and the greatest interest at present lies in the diamond-drill work, which is prospecting for the Kearsarge vein. This was discovered by diamond-drilling several years ago, and the present effort is to determine its extension and dip, and to select the most advantageous place for sinking a shaft.—The special stockholders' meeting of the Aztec Copper Co. has been postponed until August 9. The purpose of this meeting is to increase the capital from 40,000 to 100,000 shares. After this is done it is expected that a portion of the new stock will be offered for sale, thereby providing money with which diamond-drilling will be started as quickly as possible.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Two good discoveries are reported from the Center Creek land at Webb City. Two runs of ore were opened, a shallow run which was quite rich, and a deeper one more extensive and requiring a mill for treatment. Eleven drill-holes have been sunk north of Oronogo on the Poundstone farm, all entering good lead and zinc-blende.—Two good finds have been made in the vicinity of Carthage, one on the Ben Mevey land near the Tri-City Mining Co., the other on the I. C. Hodson farm, where a 24-ft. face of mineral was found at 212 ft.—The McKinley mill at Prosperity is closed down temporarily for re-modeling and enlarging.—The old Acorn tract at Prosperity, which has been idle since the burning of the mill some time ago, is to be re-opened by a new company. The ore here is rich and a large body is known to exist, there being a working face of about 1000 ft. A 200-ton mill will at once be erected, and perhaps a second one of like capacity if conditions warrant it.—The old Hockaday mill at Oronogo is being re-modeled for a tailing plant. The ore here was disseminated and difficult of separating, and hence a large percentage was lost in the milling.—The Kittle Mack Co., west of Joplin, is building a 250-ton mill which will be completed in another month. This company has sunk a shaft to the ore, which is of the disseminated sheet type found in that locality.—In the Paragon mine adjoining, the company is taking up a 10-ft. stope in the

old drifts.—A new shaft is being sunk at the Mandarin mine west of the Chicago-Joplin and a new orebody opened, so that sufficient ore can be furnished to keep the plant running steadily.—The Chicago-Joplin is operating from two shafts and is putting down a third on a drill-hole that cut the ore from 70 to 110 ft. The same company is running the Myrick mill to the east on a similar ore.

Joplin, July 24.

NEWTON COUNTY.

The Spring City camp is being materially extended southward by Adam Scott, who is prospecting a tract where zinc-blende is found in good quantities, whereas the main ore supply from this camp is galena and silicate.—A shaft on the Paul land cut an ore termed 'steel-jack' from 50 to 90 ft.—The Sunrise mill, which was destroyed by fire, is now replaced and ready for production.—Fairchild and Armil are installing pumps in an old shaft on the Armil land, where silicate and galena of good grade are known to occur at 101 ft.—The Granby M. & S. Co. has put three drill-rigs to work upon 1400 acres west of the camp.

Spring City, July 22.

MONTANA.

JEFFERSON COUNTY.

A new discovery is reported on the Boston & Corbin property at Corbin. The orebody is said to be 7 ft. wide and to contain 2 ft. of high-grade ore, the other 5 ft. being a good concentrating ore. There is much enthusiasm in Corbin over the strike.

NEVADA.

CHURCHILL COUNTY.

The Nevada Hills Mining Co. and the Nevada Wonder Mining Co. at Wonder are considering plans for the joint installation of an electric-power plant at Fallon. The Nevada Hills company is to let contracts for the construction of a 20-stamp mill shortly and sinking the shaft another 100 ft. On the 200-ft. level a large quantity of ore is blocked out on a 7-ft. vein, and two or three cars of \$100 ore is being shipped per day. W. H. Webber is manager.

CLARK COUNTY.

George Wingfield and F. J. Siebert have given up their bond on the Sproul & McLaughlin property at Fredelen, the length of their bond not having given sufficient time to prove the merit of the property.

HUMBOLDT COUNTY.

The National Mining Co. at National has opened a vein of high-grade ore and is sacking it for shipment. The adit cut the vein at a point 300 ft. below any previous workings. S. W. Gundaker is in charge of the work.

LANDER COUNTY.

(Special Correspondence).—The new 60-hp. hoist is being installed at the Frost shaft of the Austin Manhattan properties.—The drift on the 140-ft. level of the Hardy has cut a 5-ft. vein of milling ore.—The Maricopa Mines Co. is installing its steam hoisting and pumping plant at its lease on the Parrot.

Austin, July 22.

NYE COUNTY.

(Special Correspondence).—The Gold Bug Mining & Tunnel Co. has cut carbonate of copper in the Golden Gate claim at a depth of 50 ft.—Swelling of the shaft at the 400-ft. level of the Belmont crushed the 8 by 8 in. timbers last week and forced a suspension of work for several days. New timbers have been installed and the mine is again working full-handed.—The recent shipment of ore from the Clifford-Nay properties at Elendale approximated \$4000 per ton. The Pierson-Goodhue-Callahan-Hill lease report having opened a vein of \$200 ore at a depth of 25 ft. At a depth of 50 ft. a cross-cut will be driven. This lies near the Clifford holdings.—There are a large number of people in the camp, but it is evident that little work will be performed until the original locators demonstrate their confidence by sinking to fair depth.—The Fairview mine at Round Mountain is producing a fair quantity of milling ore. The vein is 4 to 6 ft. wide in the main adit.—The Morgan shaft at the Daisy is down 200 ft. A drift 105 ft.

long has been pushed from the lower level. It is intended to mine the ore by the glory-hole method.

Rhyolite, July 23.

The property of the Millett Mining Co. east of Millett is being re-opened. A. B. Millett and Paul Manuel, the principal owners, have assumed the management of the mine and mill and will have both running in a short time. Smelting returns from surface shipments have been from \$300 to \$400 per ton, and a lower adit is expected to open ore of similar value.—Several shipments from the Manuel Mining Co.'s property have been settled for on the basis of \$200 per ton by the Salt Lake smelter.—The Jingle-Clothier lease on the Tramps Consolidated property in the Bullfrog district has a 20-ton lot of high-grade ore ready for shipment. The vein is from 6 to 10 in. wide and averages \$100 per ton. The Hobo lease is working on a 10-in. vein, the pay-streak of which assays \$2400 per ton. The ore carries a large amount of manganese. The Kuliachi-Vucovich lease shipped a car of ore to the smelter at Needles that assayed \$90 per ton.

OREGON.

BAKER COUNTY.

A decree was entered in the Circuit Court at Baker City against the Oregon Smelting & Refining Co. for \$42,592. The smelter will be sold at a sheriff's sale.—The Golden Chariot mine near Sumpter is being unwatered.—The face of the drift on the Mountain View Extension property is in good ore. Frank Johnson is in charge of the work.

GRANT COUNTY.

The vein in the drift on the No. 4 vein of the Gold Bug property has widened to 3 ft., and is cutting a fair grade of milling ore. R. B. Wallace is manager.—The Kennerly Gold Mining Co. has been organized to operate the Ophir mine in the Susanville district. Considerable ore has been blocked out and the mill will be enlarged to handle the increased output from the mine. T. S. Kennerly is manager.—An excellent showing has been made on the Excelsior property on Red Boy mountain. John Smith, of Baker City, is the owner.

JOSEPHINE COUNTY.

The President has just signed a proclamation making a National Monument of the Oregon Caves or 'Marble Halls' of Josephine county, which are situated about 30 miles south of Grant's Pass. These caves were discovered in 1874 by Elija Davidson, and explored by F. M. Nickerson, of Kerby, in 1877. Five miles of openings are known to exist on the mountain and several levels have been opened. The Forest Service has re-built and improved the trails leading to the Caves, to make them more accessible.—The diamond-drill equipment for the National Copper Co. has arrived at Grant's Pass and will be hauled to the mine at once. The drill is capable of drilling 400 ft. and is operated by a gasoline engine.

UTAH.

BEAVER COUNTY.

The old Rebel mine in the Star district is being re-opened after having been idle nearly 30 years. Mat Cullen, who operated the property in early days, has taken it over and is equipping it with a complete power-plant.—Water has been struck on the 500-ft. level of the Harrington-Hickey mine, operated by the Majestic Mining Co. A new pumping plant has been ordered and sinking will be resumed. The company's smelter is operating successfully on ore from the mine.—The Moscow is shipping regularly to the Salt Lake smelter.—The adit on the Nellie group is opening a vein of copper ore that is rich in manganese.

JUAB COUNTY.

Good ore is being opened on the first, second, and third levels of the Uncle Sam mine in the Tintic district. C. C. Griggs is superintendent.—The entire Tintic smelter has been closed down for a short time to install a new concentrator and other machinery and to overhaul the plant. The ore will be shipped to the valley smelters, so the output from the Knight mines will not be curtailed.—The Scranton mine in North Tintic joined the ranks of shipping properties last week. The ore shipped from the Tintic

district amounted to 7640 tons for the week.—The shaft at the Zuma mine is down 235 ft. in a limestone formation. The company expects to cut the ore on a lime-porphry contact.—At the Eureka Hill mine at Eureka the development work is confined to the 400 and 800-ft. levels.—The Canyon Siding Mining Co. is sinking a two-compartment shaft to the 200-ft. level, from which point it will cross-cut to the vein.—Preparations are being made to commence shipping from the Eagle & Blue Bell mine.—A contract has been let to sink the shaft on the Gray Rock mine to the 150-ft. level.—A gasoline hoist has been installed at the Gold Blossom mine in North Tintic, and a compressor plant will be built shortly.—A break in some of the gearing at the Taylor & Brunton sampler at Silver City closed the plant for a few days. David Taylor, the manager, stated that the plant was handling from 700 to 800 tons of ore per day.—The output from the Grand Central and Victoria mines amounts to 9 carloads per week. Grant Simonds is manager.—The Gemini Mining Co. shipped two carloads of ore to the Salt Lake smelter. C. B. Marshall is superintendent.

SALT LAKE COUNTY.

Recent shipments from the Utah-Apex mine have been settled for on the basis of \$22 per ton. The raise from the Parvenu adit to the Andy incline will be completed about September 1 a distance of 350 ft. The smelting ore will then be shipped over the Boston Consolidated spur to the smelter and the milling ore to the Phoenix mill.

SUMMIT COUNTY.

The winze from the 260-ft. level of the Uinta Treasure Hill near Park City is being sunk on a 6-in. vein that assays 39% lead, 12 oz. silver, and \$2 gold per ton.—The Silver King Consolidated Mining Co. at Park City cut a body of lead-silver ore that assays 50% lead and 400 oz. silver at a point that gives the company 1600 ft. of backs.

TOOELE COUNTY.

The old Geyser Marion mill at Mercur was completely destroyed by fire last week. The mill had been idle for 10 years, but contained much valuable machinery. Some time ago an attempt was made to re-open the mine under the name of the New Mercur property. W. S. McCormick, of Salt Lake, and H. Otto Hanke are the heaviest losers.—M. E. King, manager for the Silver Island Mining Co., brought several sacks of silver ore from the Silver Island mine in the western part of the county to Salt Lake to be assayed, all of which ran over 200 oz. silver per ton. The ore was taken from the lower drift on the Haphazard vein, from the surface workings of which \$10,000 worth of ore was taken last winter.

CANADA.

BRITISH COLUMBIA.

The increased output of the mines in the Trail district has compelled the Consolidated Mining & Smelting Co. to blow in the fourth copper unit at the Trail smelter. This makes four furnaces handling copper and one lead ore, the combined capacity being 2000 tons per day. A record of 250 tons of lead bullion per day was made a short time ago. The capacity of the lead refinery has recently been increased to 100 tons and will be shortly increased to 200 tons per day.—The mill at the Jewel mine in Long Lake camp will be completed by September. Both mine and mill are equipped with a complete electric plant. The vein is 4 ft. wide and assays \$15 per ton gold and silver, with small amounts of galena and blende. R. Roberts is manager.—A recent sampling of the Le Roy mine yielded the following results: 47% iron, 30% sulphur, and 2½% copper, with a small amount of gold and silver.—Copper ore assaying 15%, with some gold and iron, has been opened in the Columbia Copper Co.'s property on Friday creek, near Princeton, of which E. P. Wheeler, of Spokane, is manager. The vein is 34 ft. wide.—The Canada Dredging Co. is planning to put in a dredge on Frazer river. The company has a lease on 65 miles of the river and has thoroughly prospected the ground by drilling.

ONTARIO.

Surface trenching has opened a new vein on the Har-

greaves property near Cobalt. In a 1-ft. vein of calcite 3 in. are rich silver ore with occasional kidneys filling the width of the vein.—The Lewisohns, of New York, have acquired the controlling interest in Kerr Lake Majestic property. They have also purchased the Michael claim on the east side of Cross lake, adjoining the Silver Lode property, and are credited with making good offers to purchase both Temiskaming & Hudson's Bay and the O'Brien mines.—The Nova Scotia mine in the Cobalt district has opened another calcite vein in the Keewatin formation that shows cobalt bloom and native silver. Plans have been submitted for a 20-ton concentrating plant, and it is probable that the company will be treating its own ore in a short time. A. M. Bilsky is manager.—A new Sullivan compressor has been installed at the Crown Reserve and development will pro-

State of Jalisco, Mexico.

ceed at once on the 12 veins opened on the 100-ft. level. On the 200-ft. level the main vein is 5 in. wide and assays 5000 oz. silver per ton. For the first six months of this year the output has been approximately 2,000,000 oz. of silver.—On the North Lorrain property a 6-in. vein has been uncovered a distance of 500 ft.—The drift 265 ft. west of the main cross-cut on the 200-ft. level of the Beaver mine opened a 7-in. shoot of smaltite and native silver. The ore assays 9000 oz. silver per ton.

MEXICO.

CHIHUAHUA.

The American Zinc Extraction Co. has purchased three Huntington mills and will install them at its Parral plant shortly.—The La Paz mine in the Santa Barbara district has been leased to Pablo Gaudin. The ore will be shipped to the Santa Rosalia plant.—The smelter of the American Smelting & Refining Co. at Chihuahua has resumed operations after a six-day shut-down. The tie-up was the result of a freight car getting loose on the track and running into the blast-pipe from the furnace. H. R. Wagner is manager.

DURANGO.

Frank H. Husted is purchasing a 10-drill compressor plant and cyanide equipment for his Inde and Mineral del Carmen mines. The cyanide plant is to treat ore from the Santa Lucia, Santa Eduvigis, and Campana mines.

JALISCO.

E. L. Porch, of San Antonio, has organized the La Dicha Mining & Milling Co. to take over the La Dicha mines near San Pedro Analco, and the Teddy claims in the Ameca district. R. R. Landrum is now in charge of preliminary work.—H. H. Cross and H. W. Young are erecting a stamp-mill at their property at Piginto in the San Sebastian district. There is an 18-in. vein on the property that averages 1 oz. gold per ton.

Special Correspondence.

NEW YORK.

Braden Copper.—Ely Central.—Metal Exchange. — Stock Exchange Rules.—Copper Producers Associations.

The Guggenheims are inviting applications for \$4,000,000, 6%, 10-year convertible bonds of the Braden Copper Mines Co., which is registered under the laws of Delaware. The bonds are convertible at any time within ten years from June 1, 1909, into the capital stock of the company at par. The promoters of the issue state that they have already sold \$2,500,000 worth of bonds at \$101.50, and the proceeds have been placed in the company's treasury to be used to construct a new mill and for equipment and development. The company's property is situated on the western slope of the Andes mountains, at an elevation of 8000 ft.; in the province of O'Higgins, Chile, S. A. It is distant from Valparaiso by rail 159 miles, and thence by wagon-road 35 miles. It is proposed to build a railroad from the property, parallel with the wagon-road, to join the Government railroad. The company owns 101 mining claims aggregating about 1200 acres, which contain a copper deposit of a somewhat extraordinary nature. The orebody, according to Pope Yeatman, the company's engineer, lies around the periphery of an extinct volcano in shattered and brecciated diorite, close to the contact of the diorite with a mass of volcanic tuff. The periphery of the crater is about 14,000 ft. long. The orebody surrounding the crater varies between 75 ft. and 200 ft. in width, and averages over 2½% copper per ton. The ore consists of iron and copper sulphides disseminated in the brecciated diorite and in veinlets cementing shearing planes. The deposit is being developed by tunnels. Four tunnels are now being driven, the deepest being 1000 ft. below the surface outcrop. By means of these tunnels the management estimates that over 1,750,000 tons of ore, containing 2.7% copper, have been developed. And over 2,700,000 tons of similar ore have been 'partly developed'. The company is operating a 250-ton concentration mill and proposes to build a new mill, which has been designed by Mr. Yeatman, with a minimum daily capacity of 2000 tons. Based on a daily tonnage of 2000 tons, the company estimates the cost of producing the copper refined and delivered in London at less than 8c. per pound. The company's common stock, par value \$5, has been registered for listing on the New York Curb market. The Braden is the most important American mine in Chile.

The American Smelting & Refining Co. has resumed operations at its Chihuahua smelters, Chihuahua, Mexico, after a week's stoppage caused by an explosion which destroyed a portion of the main blast and necessitated the pulling of the furnace charges. The plant is not running at its full capacity. The company does not intend blowing in the additional furnaces until the metal markets assume a healthier tone. The managing director of the Ely Central Copper Co., Ely, Nevada, has completed arrangements with a New York bank for financing the company's proposed development operations. The company's shares are becoming active on the New York Curb market in sympathy with the general attention now being given to Nevada copper-mining investments.

The Board of Managers of the New York Metal Exchange, in response to the criticisms of the Wall Street Investigating Committee, has decided to conduct dealings on the Exchange in a manner similar to those carried on by the members of the London Metal Exchange. Hereafter the minimum quantities of standard copper must be of 25 tons of 2240 lb. each. All bids or offers to sell must be made in multiples of that number. Metal classification will in future be by assay returns. Commissions are reduced to \$1 per ton when trading is done with the public, and 50c. per ton when it is between members of the Exchange. Copper stored in warehouses in New York will be considered good delivery. Negotiable receipts of copper at the following works, when they contain the clause 'Lighterage free to New York', will also be deemed good delivery: Raritan

copper refinery, Perth Amboy refinery, the Nichols copper refinery, the Balbach Smelting & Refining works, and the United States Metals Refining Co.'s works. The Governing Committee of the New York Stock Exchange also announces that it proposes to act on the recommendations of the investigating commission. It has given notice that on and after April 1, 1910, the unlisted department of the Exchange will be abolished. Among the more important unlisted stocks traded in on the Exchange are Standard Oil, Amalgamated Copper, Utah Copper, and American Smelters. It is expected that some of these stocks will become listed at an early date. Transactions on the New York Stock and Curb Exchanges during the past few days were limited in volume, but prices held fairly firm. Copper stocks moved best on the Curb market, the best demand being for Nevada and Arizona copper stocks. Cobalt stocks were heavy. Tonopah and Goldfield gold stocks moved slowly. Many of the stocks on the Stock Exchange have marked time for several days. Steel Common has been very heavy since Mr. Morgan's return from London. The market gives evidence of being top-heavy, but some traders continue optimistic and look for still higher prices.

The United Metals Selling Co., which controls the Copper Producers Association, is taking steps to extend its operations to cover Europe. It proposes shortly to issue figures covering the stocks of copper on hand at important European centres, and of the rate of consumption. It is believed that the publication of such figures will materially assist in operations in copper mining stocks on the New York and Boston stock markets. Although excellent copper statistics are published by copper dealers in London every week, it is probable that an agency termed the European Copper Producers Association will be established in London to serve up statistics for American readers.

WASHINGTON.

Taft and the Tariff.—Conservation Commission.—Land Laws.

Although the President injected himself into the tariff fight at the eleventh hour, it looks as if he had won a big victory in behalf of lower duties. The bill is still in conference. Now and then some conferee leaves the meeting in a huff, only to return later and get down to business. There were serious differences, but they are gradually being eliminated. Mr. Taft is surprising everyone at the ease with which he is accomplishing most difficult things. When the tariff bill left the Senate, there was hardly a member of Congress who did not believe that it would go through in that form, as the Senate had fought the schedules out carefully and deliberately. Mr. Taft, however, with his smile and suavity of manner proposes most astounding changes and they are accepted with hardly a murmur. To the mining interests the changed conditions of the tariff bill is interesting in the extreme. Now it is free iron ore, free petroleum, and perhaps a 40c. duty on coal without the reciprocal agreement with Canada. The changes proposed are secret until the bill is reported, but it is understood from the protests made by certain Senators at the White House that this much is the program.

The National Conservation Commission has just issued a bulletin on the progress of its work. This is the organization created by Mr. Roosevelt and repudiated by Congress, which, indeed, tacked a proviso on the Sundry Civil bill to the effect that none of the Government money should go to any commission not duly authorized by Congress itself. The commission is now conducting its investigations by the aid of subscriptions from private citizens. Under the caption, 'Need of a Definite Land Policy', the latest bulletin says: "Good business sense demands that a definite land policy be formulated. The National Conservation Commission believes that the following will serve as a basis therefor: Every part of the public lands should be devoted to the use which will best subserve the interests of the whole people. The classification of all public lands is necessary for their administration in the interests of the people. The timber, the minerals, and the surface of the public lands should be disposed of separately. Public lands more valuable for conserving water-supply, timber, and natural beau-

ties or wonders than for agriculture should be held for the use of the people from all except mineral entry. Title to the surface of the remaining non-mineral public lands should be granted only to actual home makers. Pending the transfer of title to the remaining public lands they should be administered by the Government and their use should be allowed in a way to prevent or control waste and monopoly. The present public land laws as a whole do not subserv the best interests of the nation. They should be modified so far as may be required to bring them into conformity with the foregoing."

William R. Ellis, of Pendleton, Oregon, has introduced into the House a bill providing for the temporary withdrawal of lands sought to be filed upon under the Carey act. The bill provides that whenever application is made to set aside any portion of the public domain for reclamation under the provisions of the Carey act for the reclamation of arid lands and a description of the lands sought to be reclaimed has been filed as provided by law, the Secretary of the Interior is authorized to make temporary withdrawal of the lands described in the application pending consideration of the allowance of the same. Sylvester C. Smith, Representative from Bakersfield, California, has introduced a bill providing for the acquisition of private holdings in Sequoia and General Grant National Parks. Owners of non-timber land in either of the parks, under the bill may select in lieu of their lands an equal area of surveyed unreserved, non-timber, non-mineral public lands in the State of California. The owner of any timber land in either of the parks may exchange his land for an equal value of stumpage, the timber so acquired to be harvested under the supervision of the Secretary of Agriculture. The Secretary of Agriculture is to have the power to select the trees to be cut. Ezekiel S. Candler, Jr., Representative from Corinth, Mississippi, has introduced a bill which seeks to turn over all the public domain in his State for the benefit of the public schools.

A number of interesting reports of the Mineral Resources of Alaska have just been issued by the U. S. Geological Survey, the last being reports on the progress of the investigations in the Copper River region, the Fairbanks-Yukon-Tanana and Lower Yukon regions, and the Seward Peninsula. These reports are the work of F. H. Moffit, Adolph Knopf, I. M. Prindle, F. J. Katz, C. C. Covert, C. E. Ellsworth, A. G. Maddren, P. S. Smith, and F. F. Henshaw.

ROSSLAND, BRITISH COLUMBIA.

New Dominion and British Columbia Copper Companies. — Le Roi No. 2 — Fife. — Moresby Island Copper.

The developments of the last few days in New Dominion Copper affairs point to the absorption of the interests of that company by the British Columbia Copper Co. The various mines would be worked by the consolidated concern, and the smelting works would be centralized at Greenwood, where the B. C. Copper Co. is now smelting and converting its copper at less than 8c. per pound. It was intimated at the time of the sale of the Dominion property at Vancouver that it seemed strange that the Granby, B. C. Copper Co., Consolidated M. & S. Co. of Canada, or some of the other big mining companies did not make a bid on the property, more especially as the first three named had made a bid to those in charge of the old and crippled company. It was understood at the time that the B. C. Copper Co. had offered \$300,000 or over for the Dominion Copper property, and still that same property was finally sold for \$261,000 to the Hayden interests. A consolidation with the B. C. Copper Co. would be a good move for the New Dominion at this time, and would prove of benefit to the B. C. Copper Co. It is well known that smelting operations at the Boundary Falls smelter of the Dominion Copper Co. have not been very successful, although the old company spent nearly \$250,000 in an effort to place the plant on an efficient footing. The lowest cost at which copper was made at Boundary Falls was in August 1906, when it was 0.1396c. per pound. When it is understood that the B. C. Copper Co. is both smelting and converting its copper 6c. lower, then the advantage from a smelting point can be understood. Fur-

thermore, the Dominion mines are not now in a position steadily to produce 1000 tons of ore per day, and unless such a tonnage could be shipped the company would realize but small profit on its own smelting operations. A lot of development is necessary in nearly all of the Dominion mines, and it will take considerable capital to carry this out. In a consolidation with one of the large, active companies, the New Dominion Copper Co. would get that impetus that has been lacking in the old organization; it would be a money-making enterprise for the stockholders of both companies, and would be of immeasurable benefit to the communities of Greenwood and Phoenix. At the Oro Denoro mine of the B. C. Copper Co., where diamond-drill exploration is being conducted, a large body of ore has been found 85 ft. below the present workings. The Boundary ore shipments for the week ending July 10 were the lowest for some time, namely, 17,837 tons; the Snowshoe, with 2530

British Columbia.

tons, being the only shipper besides the Granby. The ore shipments will gradually climb from now on, however, as in the course of a few days two more of the augmented furnaces at the Granby smelter will be blown in. This will make six enlarged furnaces at work, and will of course mean greater smelting capacity. The six new furnaces treat 750 tons per day more than the old battery, the entire set of eight enlarged furnaces increasing the smelter capacity to 4500 tons per day, or 1000 tons per day more than under the old system.

A 20-hp. motor has been connected with the electric hoist at the Tip Top and Bay mines and development resumed. There is a 150-ft. shaft on the Tip Top, and some driving has been done on the 125-ft. level. A good strike of 15% copper has been made on the claims of the Columbia Copper Mining Co. on Friday creek, near Princeton. The lead has been pierced for 34 ft. on one side of Friday creek, and 71 ft. of tunnel has been driven on the opposite showing. The Le Roi No. 2, Ltd., has declared another dividend of 2s. per share (48.6c.). As a like dividend was paid by this company in March, they have paid in all over 97c. per share in dividends this year, and it is expected that as much more will be paid from the earnings of the current year. A new 8-in. lead of heavy ore has been found on the Blue Bird claim. This was on the northern part of the property, and is widening with depth. On the Richmond group, nearby, which is being worked by a local syndicate, a new lead of carbonate ore has been uncovered, from which assays of \$38 per ton have been taken. On the Jessie F. property, Norway mountain, the owners now have about 135 sacks of ore ready for shipment, assays from which have gone as high as \$400 per ton. Active development is going

on at the Fife mines. The ore is low-grade, similar to that found in the immediate vicinity of Rossland, containing 3 to 6% copper and \$3 to \$8 in gold. A couple of cars of ore, now available, will be shipped to the Trail smelter in the next few days.

A force of 20 men is at work opening the big copper deposit on the Contact group, Moresby island. A. B. W. Hodges, resident manager of the Granby, and his associates, recently acquired control of this promising property. It is expected that the Moresby copper deposits will outclass those of the Boundary when once thoroughly opened. In addition to being rich in copper and assaying well in gold, this ore is almost perfect for smelting, and then there is the advantage of water transportation. One prominent mining engineer has said that the conditions are ideal. Work is also to be done on the Swede group, owned by Johann Wulffsohn, of Victoria. If certain concessions can be obtained from the Provincial Government, Henry Phipps and associates, of the U. S. Steel Corporation, will spend several millions of dollars in the development of the coal areas of Graham island. Mr. Phipps and party were recently over the ground.

MEXICO.

Cinco Minas, Jalisco.—New Mills. — Jalisco Coal. — Tuxpan River Oil.—Pipe-Line to Mexico City.

Jalisco, and particularly the district of Hostotipaquillo and Etzatlan, may well feel jubilant over the reversal by John B., George E., and Fred. Farish of the opinion given by E. A. Wiltsee on the Cinco Minas in Hostotipaquillo and the resumption of work thereon by the Marcus Daly estate. The black eye given the property by Mr. Wiltsee would have had a most serious effect on many surrounding properties, and it would have taken a long time to overcome it, but now with a resumption of operations, including preparations for a 250-ton mill (probably cyanide), everyone in that district may breathe more easily. It is doubtful if any district in Mexico, distant from the railroad as it is, has shown such marked forward strides in development recently as has Hostotipaquillo in the last three years. It has been a natural, healthy growth, encouraged greatly, of course, by the contemplated extension in that direction of the Southern Pacific's Guaymas-Guadalajara line, which is now rapidly approaching. The train service is now in force between Orendain and Tequila, and by the end of the year it will be extended to La Quemada, near Tequesquite, and but a short distance from Hostotipaquillo by wagon-road. But the ores are amenable to the cyanide process, so the development and extraction is not so absolutely dependent on the railroad. More important, however, is the question of power. Electric current will be furnished over the wires of the Manuel Cuesta-Gallardo combine from the plant on the Santiago river, near Guadalajara, before the end of the year. A new 12,000-hp. plant of the Siemens-Schuckertwerke system will be erected on the Santiago river near the Totolotlan bridge. El Favor Mining Co., of Hostotipaquillo, is putting in 20 stamps, with concentrators, tube-mills, and cyanide, figuring on having all in running shape by the time the electric power reaches there. The Virginia & Mexico Mining & Smelting Co. has its 150-ton mill, the first large mill in the Hostotipaquillo district, also stamps, concentrators, tube-mills, and cyanide, about completed, and will run by steam until the power-line is in. F. G. Stevens, formerly in charge of El Favor, but now superintendent of the Mololoa, is trying to persuade the owners of that property to put in a 100-ton mill. A. J. Vick has interested San Antonio capital in opening up the Deseada. At San Sebastián, about 50 miles southwest of Hostotipaquillo, near the Tepic line, the Tajo Mining Co. has completed its primary 30-ton stamp and cyanide mill, and will begin work on ore, from the upper tunnel, running about 30 oz. silver, and 0.2 oz. gold, but as soon as the lower tunnel reaches the vein, at a point 200 ft. below the old workings, the mill will be added to and enlarged as development warrants. At the Tenamache mines, north of Santiago Ixcuintla, in Tepic, the machinery is on the ground for a 50-ton mill similar to those being erected in the Hostotipaquillo district. The

Tenamache mines are controlled by W. R. Ramsdell, who is also largely interested in Hostotipaquillo. The completion of the Southern Pacific Guaymas-Guadalajara line is of primary importance to Jalisco, Tepic, and Sinaloa, and it, together with the Mexican Central branch to Manzanillo, will give outlets for the ores to the smelters by either land or sea. Both roads will also open markets to the Jalisco coalfields, which are opening up to some importance in a district about 18 miles east of Zapotiltic, a station about 113 miles from Guadalajara on the Manzanillo branch of the Mexican Central. The coal is a clean, non-coking lignite, the highest ash so far being only 8%. It occurs in seams from 14 to 40 in. thick, with a very slight dip. The drilling has proved some 2000 acres, and the outcrops would indicate a productive field of at least 8000. Further prospecting may extend this.

In the Coahuila coalfields the labor roll has been considerably added to since the new freight rates on foreign coal and coke went into effect, and it is predicted that by the middle of next year the roll will be more than double what it was before the introduction of the new rates.

Of the more recent work in the various oilfields: though Mr. Harriman has struck oil on the Tuxpán river in Vera Cruz, as previously mentioned, at a depth of 2900 ft., it was not in paying quantities, and even now at a depth of 3300 ft. there is no great improvement; whereas the Pearson wells, farther up the Tuxpán river, show up well and strong. The Pearson's work in Tabasco, however, spread over a period of four years, and with an expenditure of some \$2,000,000, seems to have been a failure, for out of the 15 wells drilled, not one can be called a good producer, and the work for the present has been abandoned. E. L. Doheny, president of the American & Mexico Petroleum Co., has raised about \$1,000,000 for the construction of an 8-in. pipe-line, with pumping stations, between Ebano, San Luis Potosí, and Mexico City, a distance of 105 miles, which he hopes to have completed early in 1910, and which will be used to furnish oil for making gas to supply Mexico City. The company has at Ebano 15 producing wells with an output from 100 to as high as 8000 bbl. of oil per day from one well. There are 12 others being drilled. It is one of Mexico's important fields.

BUTTE, MONTANA.

North Butte — East Butte. — Amalgamated Labor. — Zinc.—Raven Copper.—Snowstorm.—Butte Extension.

The interesting feature of the North Butte now is the Jessie vein, expected to be reached by the cross-cut on the 2200-ft. level about October 1. Connections are to be made with the Boston & Montana company's Badger State shaft, which is being sunk to reach the extension of the Jessie vein. The North Butte company is raising on the 1200, 1400, and 1600-ft. levels in the Granite Mountain, which it bought some time ago. The Lewisohns, who sold the Edith May, thought they had a big mine in the Granite Mountain, but after sinking the shaft to the 500-ft. level, dropped it. The North Butte expects to complete its second working shaft by January 1, 1910.

The East Butte is smelting 400 tons of ore per day at the Pittsmont smelter, and has put in commission one new furnace and one old one. The Pittsmont company was unable to develop any ore reserves while mining, the ore being extracted to pay expenses as fast as developed. The East Butte went to great expense to run a long cross-cut from the bottom of the main shaft on the 900-ft. level to tap the Glengarry vein, cutting a number of small veins of little value in the intermediate territory, and opening a water-pocket that drowned out the miners and suspended everything but pumping. Competent mining men believe that the company will have to go down to the 1800 or 2000-ft. level to properly develop the mine, and had the money spent on the long cross-cut described been used to sink the big shaft, No. 11, near the Glengarry vein, to the 1500-ft. level, that would have determined the value of the vein. Although the No. 1 shaft is down to the 900-ft. level, the developed territory from the surface to the 400-ft. level shows only ore of low grade.

The Davis-Daly Estates company is shipping 100 tons of ore daily from the Colorado shaft. The vein is being worked on the 1200 and 1400-ft. levels, and a winze is being sunk from the 1400 to the 1500-ft. level to the west. The vein runs northeast and southwest, and the work is all in good ore. It is the policy of the Amalgamated Copper Co. henceforth to employ American labor in place of foreign, when possible, and to give the men from the countries in northern Europe preference over the Slavs, Austrians, and Montenegrins. The company has experimented with the latter labor for several years, and found it unsatisfactory. The rule will apply to the mines as well as the smelter of the company, it is understood. The south Europeans are said to work hard, but they lack the intelligence of American and northern European laborers. The stock of the Butte-Balaklava Copper Co. will be listed on the Boston Stock Exchange, the stockholders lately having taken steps to dissolve the trusteeship.

It is reported here that the Clarks have found a successful method of treating the zinc ores of Butte, and it is

half as a result. Butte people are puzzled by the unusual stories from the Greenoughs and the passing of the dividend. The report of the general manager, F. H. Cooney, of the East Butte Extension Copper Co., says that lessees are working the mine day and night on development, and that the debt of the company is less than \$4000, with practically no current expenses. The company will elect directors on August 15. The McKee group of mines in Madison county has been sold for \$32,000 cash. They are situated at Meadow Creek, and the purchasers, W. R. Allen of Montana and a group of Chicago capitalists, will develop them extensively.

NOME, ALASKA.

Russian Laborers.—Nome Surf.—Tuluksak Stampede.—Cape York.

The steamer *Victoria* from Seattle arrived June 12 at Nome with 387 Russians. They were allowed to land, but the city authorities, aided by the customs officials, deported a bunch of them on the next steamer. Many were destitute

Front Street, Nome.

given out on good authority that W. A. Clark and his son, W. A. Clark, Jr., will build a large mill here.

The new Raven Copper company, organized in Maine, has taken over the property of the Raven Mining company, the transfer having been made here by the stockholders lately at a special meeting, at which more than two-thirds of the stock was represented. The new company pays \$50,000 into the treasury and takes the property, subject to the mortgage of \$65,000 and interest, the \$20,000 floating debt to be lifted with part of the money paid into the treasury. Old stock may be exchanged by paying 25c. per share for the new, the old being given a value of 50c. per share, before August 31. The 370,000 shares of old stock in the treasury will be replaced by an equal quantity of new. The president of the company received a telegram from Boston saying that owners of 510,000 shares of stock have paid the 15c. per share payable by July 19, many paying in full. It is expected that work on the mine will be resumed within a month, when the incline will be sunk to the 1500-ft. level and cross-cuts be sent out on the 1300 and 1500-ft. levels.

The conflicting reports about the condition of the Snow-storm mine at Wallace continue to interest Butte people. The latest story emanating from the Greenough camp is that the railroads are trying to hold them up with excessive freight rates, and that ore shipments will be cut in

and were arrested and placed in the local jail as vagrants. Who imported them is yet uncertain. Some of them have secured work with Fleming Bros. & Hanks, the Pioneer, and other companies. Work of the season is now well under way. The Nome Surf Mining Co., backed by Tacoma capitalists, is installing a steam-scraping plant along the shore of Bering Sea, sanguinely expecting to make large clean-ups of beach gold from the surf-washed concentrates. In 1905 and the year previous, several similar ventures proved failures, and the wrecks of their exploitation may still be seen half buried on the beach. A recent attempt to dredge in the same place by Lane's big scoop dredge proved the ground under the sea to be frozen a few feet below the surface. The bedrock tunnel from Iron creek to Pilgrim river, put in by Waskey & Co., is completed and in operation. The detritus is dumped into Pilgrim river and carried off by the current. Good results have been obtained from the work inaugurated. Fred. Lind, a quartz miner of Nome in 1901, committed suicide at Cordova on June 25, by shooting himself in the head. Walter E. Clark, the new Governor of Alaska, was a Nome beach miner in 1900, and is well known here. Lutschinger's submarine mining venture with Russian lessees has proved disastrous. They lived extravagantly, worked leisurely, got money and machinery for operation of a local bank, and then deserted the dump,

which the bank ascertains is hardly worth sluicing.

Several discoveries of rich ground are attracting attention. The diggings on the Tuluksak, a tributary of the Kuskokwim river, are reported as being rich by arrivals from that region who have gold dust, and are buying outfits to return. A big stampede is occurring from Nome, and every conceivable kind of craft is being chartered. Nome will be depopulated if the stampede keeps up till fall. Bangor creek, tributary of Snake river, near Nome, is the scene of an important placer-discovery. A streak of gravel 3 ft. thick, averaging 4c. per pan from rim to rim, is being ground-sluiced. The Cape York Tin Mining Co., Andy Baumgartner, manager, is being surveyed so that it may be patented. Several new stringers of cassiterite ore have been cut by a tunnel 100 ft. into the mountain. The main vein is expected to be intersected before the close of navigation. An attempt to mine for rubies will be made on the Bluestone river near Teller. H. A. Ring has orders from an Eastern firm for \$100,000 worth of the uncut stones to be delivered in Seattle before the close of navigation. Rubies in the rough have been selling in Nome for 50c. each for years. These came from several creeks near Gold Run. Quartz mining is looking up, and many reputed valuable locations are recorded with the U. S. Commissioner's office. The Connolly mine and recent extensions will be dropping stamps before August by water-power on Gold Bottom creek.

GOLDFIELD, NEVADA.

Ore in Clermont Shaft. — Consolidated Development. — Activity of Lessees — Mining Congress.

The discovery of a large body of good ore at a depth of 730 ft. in cross-cutting from the Clermont shaft is regarded as vitally important, not only to the Consolidated Mines Co., but to the entire Goldfield district, in its influence upon future operations and in confirming the belief that the ore-bodies of the district will be found to extend to great depth. J. H. Mackenzie, the manager, who is always reticent and extremely cautious in speaking of new developments, says that the ore carries not less than \$30 per ton gold, and that it is distinguished in character from most of the company's ores by the absence of base material and by being more readily amenable to milling. It is now known that much of this ore is far more valuable than was indicated by the first announcement. The find is believed to be a downward extension of the rich Macmillan ore-shoot from which the Mohawk-Jumbo lease, on the Gold Wedge Fraction, took nearly \$200,000 worth of high-grade ore. The statement has been made by a miner employed in the Clermont workings, but lacks confirmation by the company officials, that the cross-cut from the 1000-ft. station of the Clermont shaft has passed through 40 ft. of a vein in which free gold is plentiful, and samples from which run as high as \$125 per ton.

The two mills of the Consolidated Co. are treating over 700 tons of ore daily, the mill-heads being maintained as nearly as possible at \$27 per ton, and no high-grade ore is being extracted from any part of the mines, all being left standing or, when necessary to break it down in the course of development, stored in the workings until the time when it is required for mixing with the low-grade product. A winze is now being sunk in a large body of good ore from the 600-ft. level of the Mohawk mine; at the 403-ft. level the stopes have exposed a large tonnage of exceedingly rich ore with large seams carrying as high as \$10 per pound; the big vein to the east of the shaft is being further explored. The stopes to the north of the shaft above the 400-ft. level are proving up some large bodies of mill-ore, together with high-grade, and the great deposit at the southeastern extremity of the claim is being blocked out by stopes and raises between the 400 and 600-ft. levels. The principal tonnage for the big mill is still coming from the Mohawk. There has been a constant improvement in the 260-ft. south drift from the Red Top and the connecting stopes extending into the Lucky Boy, from which a large and even production is being made, and particular interest attaches to the results of driving from the Clermont shaft at a depth of

600 ft. for the extension of this orebody. Good ore has also been exposed in driving north from the Red Top shaft.

During the past fortnight there has been a marked revival in mining operations throughout the Goldfield district, as a result of developments on the Consolidated, Daisy, Belmont, Great Bend, C.O.D., Velvet, and Victor. Upon all of these rich ore has been developed at entirely new points. The revival has manifested itself primarily in the resumption of operations on territory that has been idle for some time and in many applications for leases upon undeveloped ground. On the C.O.D. work will begin at once at two points. Thomas A. Lister, who is operating at Lordsburg, N. M., and who formerly conducted the Goldfield Fargo lease on the C.O.D., has arranged to resume work and sink to great depth. He has also obtained from L. K. Koontz, manager of the C. O. D. Consolidated, a three-year lease on the eastern portion of the same claim, embracing a portion of the old C.O.D. M. & L. ground, upon which he has lately found some high-grade ore in prospecting near the surface. This block yielded a fortune from a shallow shaft near the eastern boundary in the camp's early days, and the new lease will begin operations as a shipping enterprise. Philadelphia operators have secured two leases under terms requiring them to sink 1000 ft. at once, on the Poleverde claim, the joint property of the Consolidated and Jumbo Extension companies and adjoining the Clermont and Velvet claims. Both these shafts will be of two compartments and timbered in substantial manner. On the Laguna driving is in progress from the 720-ft. level of the old Hazel shaft by the Chicago Cleveland Co., under the management of William MacKay, who found the rich ore in the bonanza Frances-Mohawk lease. Small seams of good ore have appeared in these workings at 718 ft. depth. Specimens of oxidized ore, spotted and sprinkled with free gold, are being taken from the old Detch-Brewer stopes on the Daisy, 65 ft. deep. The ground was taken under a sub-lease by Bruce Jones and Guy Millard, upon a 50% royalty basis, and they have already stripped 20 in. of exceedingly rich ore for a distance of 8 ft. with three days work. Shipments of \$105 ore are going out from the recently exposed ore-shoot at 360 ft. depth on the Golden Daisy lease. The Daisy company has found good ore in the original incline shaft near the eastern boundary. Some of this ore is now being included in the daily shipments, and driving is in progress from the main workings toward this orebody. North of the Daisy 800 ft. and on the extension of the main cross-fissure of the Daisy, shipping ore averaging around \$100 per ton is being mined at a depth of 62 ft., on the Goldfield Belmont, by lessees working the upper levels of the company shaft. Since this ore was found the company has started work at a deeper level and is seeking the same orebody.

Three shafts belonging to lessees on the Atlanta are now in the dacite, with assays showing low-grade mill ore at several points. The Fairview-Cherokee has let a contract for 100 ft. additional sinking from the 500-ft. level, and may continue to 800. The Precious Metals lease has milling ore and is sinking. The Maloney lease is developing at 630 ft. and several others are preparing for development at depth. The Golden Pick lease on the Pipe Dream claim of the Silver Pick, adjoining the Combination, is driving north and south at two levels in a strong quartz vein. Sinking is in progress at three points on the eastern slope of Vindicator mountain, by the Gold Button Co. and two lessees on the Talmage group. On the Red Mountain belt the Nancy Donaldson shaft has been timbered to the 100-ft. level, and is being sunk to depth with good ore in sight in narrow seams.

The keenest interest is being manifested throughout the State in the forthcoming session of the American Mining Congress, which meets in Goldfield on September 27. Commissioners have been traveling over the State, visiting the various mining district and soliciting specimens for a mineral exhibit. Samples are arriving daily from various camps, and are being assorted and classified by experts. It is now apparent that this will be one of the best collections of ores and minerals ever assembled in the country. The Consolidated has hoisted from the 403-ft. stopes of the Mohawk mine, for this exhibit, two blocks of high-grade ore each weighing 500 lb. and said to be valued at \$15 per pound.

JOHANNESBURG, TRANSVAAL.

Speculative Mania.—Haphazard Pegging.—Labor Shortage.—Mechanical Ventilation.—Output Record.—Rand Yield to Date.—Safety Regulations.

For many months the share market has been gaining strength, and its condition has been so remarkably buoyant during the last two weeks as to gain from the excitable or hopeful the appellation of a 'boom'. Fortunately, no real 'boom' has yet arrived, and although many of the more speculative stocks are five or ten times as high in price as a year ago, the advance has been gradual over a number of months, with occasional 'healthy reactions'. Stock exchange conditions are rarely dealt with in these letters, but there are times when they assert themselves forcibly. Such is the case at present. The turn of the tide in the financial world has created a spell of almost unexampled activity. Johannesburg is wonderfully busy. Geologists are visiting properties in all quarters and are endeavoring to discourage their principals from attempting impossible chances. Others are flying to option farms and cheerfully refuting, with characteristic confidence and breadth of view (regardless of detailed facts), the existence of 'Main Reef' extensions at shallow depth below the coal measures, dolomite, 'Black Reef', or what not. Mining engineers are busy with schemes for expansion honestly proposed by the controlling 'houses'. Mechanical engineers are overwhelmed with the sudden mass of work falling upon their shoulders in connection with the electrification of the industry. 'Peggers' are out all over the country. The Government will reap a big harvest (for a few months at least) in license money in respect of the many thousands of claims staked by ignorant enthusiasts for whom every stretch of conglomerate means a potential Robinson and every float boulder the trusted marker of a sub-outcrop of the Main Reef. Of course the crash must come, but such is the dazzle of the Kaffir market, with all the lights turned on, that it is difficult to prophesy the limits of the excitement.

That there are many favorable features presented by recent developments on the Rand is true. The good grade exposed in the City Deep—with its million tons of \$8 ore over 3000 ft. deep—and the favorable results obtained in the basin of the Far East Rand, are a 'host' of good news in themselves. Further, the gold-content of the South Reef and the Main Reef Leader shown in the Turf shaft at 3900 ft., though not high, is payable, being about the same as that of the Village Deep above. The labor position, at one time the all-important factor, has for the past year been allowed to pass out of calculations. It requires but small foresight, however, to perceive that the obstacle to progress presented by scarcity of native labor will soon be seriously felt. With a shortage prevailing for the mines already producing or developing, the conceivers of bold schemes for the conversion of thousands of idle reef-bearing claims in the Far East Rand into active properties should at least ponder the possibilities of labor difficulties.

The artificial ventilation of Rand mines on an extensive scale has been discussed intermittently for at least ten years, and its economic possibilities have been frequently enunciated. While its ultimate necessity in the deep-level mines of the future has been fully recognized, its advantages in the mines of today have not been. The ventilation of the lower levels of the East Rand Proprietary Mines having been poor when natural means were relied upon, some parts of the property being so notoriously bad that it was impossible to get good miners to remain at work in them, it was decided some time ago to put in a Sirocco fan. The success of the innovation attracted fresh attention to the benefits accruing from good ventilation, and it is probable that the lead set by the E. R. P. M. will be followed by other companies. The fan was 10½ ft. diam., with a capacity of 300,000 cu. ft. per min. at 4-in. water-gauge. The Transvaal Government Regulations call for a supply of 70 cu. ft. per man per minute. Generally speaking, the mines of the Rand have been fairly well off in the matter of natural ventilation, which is favored by the regular schemes of development

and the steep dip as compared with the coal mines. The increase of rock-temperature with depth has been too small to make the demand for artificial ventilation urgent, and the strata have not flattened as rapidly as was anticipated. It is undeniable, however, that the good reputation of the Rand's natural ventilation has been responsible for allowing neglect in individual cases. Since the discussion between chemists and doctors in 1903, the intimate association between mine-gases and those fatal sicknesses to which the Rand miners are liable has been universally acknowledged. For many years the cry of those anxious to fight for the miners' protection of health has been, "water for the dust; ventilation for the gases."

The Transvaal gold output for May establishes a new record. The aggregate of £2,652,699 surpassed the previous record, for December 1908, by the narrow margin of £956, when allowance is made for the withdrawals from gold reserve included in the 1908 declaration. The yield for the first five months of the current year now reaches £12,825,729. It appears probable that the yield for 1909 will exceed £32,000,000. Much depends on the labor supply. The decrease in May was 4622 natives, and 7700 Chinese will soon be repatriated. The magnitude of the winter exodus of Kaffirs to their kraals will be an important factor in determining the speed with which schemes of output expansions may be accomplished. The Government has been trying to obtain a mine to be used as a training school for miners, in accordance with an arrangement entered into with the Chamber of Mines, but has so far failed to find one which would be satisfactory.

The Transvaal Chamber of Mines has issued its usual report for the year 1908, which is full of interesting and suggestive points for those with the leisure to peruse its voluminous pages. The total declared output of the Rand, together with the unrecorded yields for certain periods, is given at 50,785,785 fine ounces, worth £215,724,300, from the industry's inception to the end of 1908. Adding the returns for the first five months of this year, we arrive at an aggregate exceeding the enormous figure of \$1,120,000,000.

Mr. Fergusson's paper before the S. A. Association of Engineers, on the relation of safety to economy in mining, though lacking in point and decisiveness, has led to serviceable discussion. It is generally conceded that Mr. Fergusson's estimates of financial loss through accidents were conservative, and failed to represent the magnitude of this ill-defined debit. Apart from serious accidents, duly reported to the Government Mines Department, there is a host of minor accidents, which appreciably reduce the efficiency of the labor complement. The attitude taken by the Government Mines Department is that of encouraging or forcing the companies to increase their supervisory staff, and to make the question of underground safety the special care and responsibility of some competent person or persons, instead of allowing it to be one of the many matters for attention comprising the daily routine of the shift-boss. The suggestion expressed, semi-officially, by Mr. Kotze (Government Mining Engineer) that the Mining Regulations were to be expanded in regard to necessary measures for the prevention of accidents, has not been welcomed in mining circles. It is declared anew that the Rand Industry is sadly 'over-regulated', and is burdened with more official injunctions as to the things to be done or not to be done than any other mining district in the world. In regard to certain aspects of underground work, the Australian regulations are probably as detailed and onerous. There is good cause for complaint, however; fewer regulations more strictly and rationally enforced would be more suitable to Rand conditions than the existing miscellany.

At the last monthly meeting of the Chamber of Mines, the President made the satisfactory announcement that the Chamber would soon be in a position to erect a Miners' Phthisis Sanatorium. While prevention is better than cure, and every effort should still be made to check the ravages of this disease, the seriousness of which can scarcely be realized by mining men in other fields, the establishment of such a Home will serve a good purpose, and, by providing the needful attention to the sick, may be the means of saving many miners.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cinnabar occurs on Palmer creek, in Oregon. It has been found here only in stream-gravels, and has not as yet been traced to its source in the surrounding rocks.

Aluminum is difficult to solder, and welding with the electric arc is better; but a solder consisting of 45 parts tin and 15 parts aluminum may be used successfully if the surfaces to be united are previously cleaned of the film of aluminum oxide by abrasion.

Insulation of electric wires underground is extremely difficult. Up to 300 volts at least it is better to use bare wires, and many engineers consider that 500 and 600-volt feeds had best be installed bare, but so placed as to guarantee the maximum amount of safety.

Direct-current cables for transmission in mines should be concentric with the inner wire negative. To prevent fire spreading in case a cable should break down, the cable should be wrapped with asbestos strips about 3 in. wide and $\frac{3}{16}$ in. thick, the strips soaked in a solution of silicate of soda and wrapped on while soft.

Barium chloride is sometimes used for softening boiler-water. It transforms sulphates of the alkaline earths into barium sulphate and the chloride of the earthy base. Barium sulphate does not form hard scale, as does calcium sulphate. When magnesium sulphate is present, magnesium chloride is formed. This is an extremely corrosive salt.

Hard iron ore from Clinton horizons in the Birmingham district of Alabama is generally high in lime. Such ores on weathering yield a soft ore rich in iron by the process of residual concentration. With the exhaustion of the rich outcrop ores the hard ore has come to be used in larger amounts. The fact that it is high in lime and low in silica makes it available as a flux for the brown ores of the region.

Tonopah ores are essentially silver-bearing, the ratio of silver to gold being as 100 to 1. Both oxidized and sulphide ores are worked. Zinc, manganese, and copper are present in all the ores, but not in quantities sufficient to interfere with cyaniding. At the Montana-Tonopah mill the method of fine-grinding and agitation is the same as that so widely and successfully applied in Mexico.

Limestone in regions subjected to excessive metamorphism or to volcanic activity, is often altered by the action of gaseous emanations and infiltrating waters. Profound changes may occur in the chemical composition of the limestone without revealing the alteration to the eye. This is especially the case when silica has been introduced. Limestones may in this manner develop a great variety of crystalline silicates, such as garnets, pyroxenes, hornblendes, magnetite, spinel, titanite, tourmaline, apatite, and others, so as to superficially resemble altered forms of igneous rocks.

Basaltic columns are caused by the development of jointure in igneous rocks on cooling. The resemblance to crystalline form is only incidental, not structural. The number of sides of the prism may vary from three up to six. The longitudinal axis is always perpendicular to the surface of cooling; hence in effusive lavas it is vertical; sometimes the columns radiate from centres in a fan-shape; while in dikes they are perpendicular to the walls. Columnar habit is not confined exclusively to basalt.

Briquetting machines vary in capacity with the design and size. The Johnson machine used by the United States Geological Survey in testing had a capacity of 6 tons of briquettes per hour when making rectangular blocks $6\frac{3}{4}$ by $5\frac{1}{2}$ by $4\frac{1}{4}$ in., weighing 6.8 lb. each. When making briquettes $6\frac{3}{4}$ by $4\frac{1}{4}$ by $2\frac{1}{2}$ in., weighing $3\frac{3}{4}$ lb., the capacity was 3.8 tons. The Renfrow machine, making cylindrical briquettes with convex ends, measuring $3\frac{1}{4}$ by $1\frac{1}{2}$ in. and weighing 11 oz. each, had a capacity of 8.9 tons per hour.

Mine fires in European mines have in the past been the cause of loss of life. In Germany, at much expense, elaborate fire-fighting facilities are provided, resembling in every particular a well appointed fire-brigade station such as is maintained by some of our cities, having fire-engines, horses, and a crew of trained men. Many stations are equipped with different types of rescue apparatus and men trained in their use. In Austria a law requires that each mine shall be equipped with such apparatus, and at all times a certain percentage of the under-ground employees shall be trained in its use.

Safety lamps in England are carefully inspected before being taken into the mine, and upon reaching the bottom of the pit a mine official makes a second inspection of the lamp to see that it is in good condition. It is forbidden to set a safety lamp on its bottom in any part of the mine. When a workman wishes to place his lamp to one side, he must hang it in a safe position. In Belgium the lamps are looked over by an official on the outside of the mine, to see that all of its parts are properly assembled. In Germany the lamps are handed to the miners cleaned and locked. They examine them to ascertain if they are in condition suitable for use.

Volume changes as a result of metamorphism are unimportant in the Hanover, New Mexico, district. In those beds less susceptible to pneumatolytic changes the alteration has been of the nature of re-crystallization, with possible silicious additions. Apparently the purer limestones, as the carbon dioxide was driven out, were invaded by magmatic solutions at high temperature, and any tendency toward shrinkage was counteracted by accessions from the magma. The elements native to the intruded rock, such as lime and silica, which were of a proper nature to form contact minerals, combined with materials from the magma, the whole forming a solution from which the present minerals originated, and the newly crystallized rock occupying the same bulk as that which was antecedent.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Comstock Bullion.

The Editor:

Sir—In your issue of July 3 you speak of the Comstock Lode as a silver lode, and intimate that Mark Twain was a product of Comstock bonanzas, while the truth is that the Comstock bullion was nearly as rich in gold as in silver, and the world is indebted to a Comstock borrasca, and not to a bonanza, for Mark Twain. Mark Twain left the Comstock because at the time he could not find work to do. As to 'Who shall balance the scales and say which has contributed the more to the joy of the world?', Mark or the three hundred and fifty million dollars, the task is easy. Mark takes the prize, for when the Comstock's millions are charged with the tears that were shed and the blood that was lost in their winning, it will take a large part of the untold millions that the old lode can yet be made to yield to put the account in decent shape, while in the life and works of Mark Twain it may be said of such parts that are not all joy, that his "sweetest songs are those that tell of saddest thought."

To return to the Comstock bullion: while it has ranged from 1½ to over 50% of gold, the bulk of the output contained 40% in value of gold. The mines of Cedar hill yielded bullion worth over \$10 per oz.; the mines of Silver City still yield such bullion—Cedar hill being the north and Silver City the south end of the Comstock. The placers in the canyons from the north to the south ends of the lode still yield gold bullion.

The mistake in speaking of the Comstock's output as silver is natural, as it is not long since Nevada was known as 'The Silver State'. They had a silver party there, and professed to believe that the builders of the Republic were right when they wrote into the Constitution: "No State shall make anything but gold and silver coin a tender in payments of debts." But now it is taught that the nation has outgrown the Constitution, and that the Declaration of Independence was an iridescent dream. Even in the midst of such teaching it were well to hold on to the multiplication table and obey the Constitution until the wise men are prepared to submit in the manner duly prescribed, a better Constitution. There seems to be no logical objection to the closing appeal in Judge Fitzgerald's work, 'The Thirty Years' War on Silver,' when he says: "But when the days again come when the Constitution of the United States is observed and obeyed in the letter and in the spirit, there will be then days of gladness. Then will prosperity smile in the valleys and upon the hills and upon the mountains. Let the people honor the principles and obey the precepts of their fathers, that their days may be long in the land which the Lord their God hath given unto them. Honored be the men and women who shall aid and guide them to the observance of

the principles and in obedience to the precepts of the fathers as they are expressed in their Constitution of Government."

Stockton, California, July 21.

The Sacramento Anti-Dredging Convention.

The Editor:

Sir—It may be of interest to some of your readers not in touch with local events to see how the prejudice of the farmer against the miner was again revealed when the delegates to the Anti-Débris Convention assembled this week in the city of Sacramento for the purpose of discussing the effect of dredge-mining upon the farming industry. From the course of the discussion the word 'discuss' must here be taken in the sense of 'to break up; to drive away', and not in the sense of 'to examine in detail'. The relation of this phase of the mining to the farming industry is such that in every instance when extensive dredge-mining is carried on, the ranches and the towns have been directly benefited, and today great activity and prosperity are found in districts which were almost dormant previous to the advent of the dredging companies. The cause of the quiet tone of the meeting may be found in the fact that some of the delegates were in harmony with dredging, due to their having investigated conditions before going to the meeting. All of the delegates were invited, and every facility was offered them to investigate and see the existing conditions for themselves, but only a few cared to do this. Some came to the meeting without ever having seen a dredge or the conditions in the field. However, one delegation which did go witnessed the blasting of a hillside into the Feather river along the Western Pacific railroad, and saw men employed in shoveling broken rock and dirt into the stream, the very thing the dredges are condemned for doing; yet the contention at the meeting was that dredge-tailing obstructs the streams and is the cause of the destruction of a great deal of land by floods. As there are no dredges working directly in the rivers, excepting those performing assessment work on the Yuba river, this can not be true. In any event, it would be impossible to place the blame for these floods on any one industry without extensive investigations extending from the headwaters of the various streams down to the overflowed territory.

One speech had for its base the destruction of the land for all time to come, affirming that 800 acres of the greatest vineyard in the world was being sacrificed, that choice valley land was being permanently blighted, and finally, that most of the money derived from these operations is sent away to Eastern stockholders. Merely casual inquiry would prove how unfounded and prejudiced is such a statement. At the place referred to, for every acre of vineyard dug up two acres are being planted on adjacent land owned for this purpose, and finally, when all of the 800 acres shall have been turned over, the ground will be leveled and a new vineyard planted. It is a proved fact that vines planted on dredge-tailing produce fruit that matures earlier and has a better flavor than that grown on ordinary soil. It also re-

quires a smaller percentage of water on dredge-tailing. The choice valley soil that is being 'blighted' will also be made productive, and where nothing grew before, in the future it will be utilized for farming. It is also an established fact that eucalyptus, fig, orange, almond, and many other trees, do well and grow rapidly, even on unleveled dredge-tailing, requiring no fertilization. One has only to visit J. H. Leggett's place at Oroville to see a demonstration of these things.

Furthermore, the dredge cobble-stones are being removed to crushing plants on the railroad for ballast. In the Folsom district alone are two large rock-crushing plants, and it is safe to say that if the county of Sacramento will use the crushed rock from these plants for road construction, in a few years there will not be a pebble left on the dredged area above the natural level of the ground. At Oroville there is one rock-crushing plant, and the railroads have acquired several hundred acres of dredged land and are hauling the cobbles away for ballast. At the present rate it will not be many decades before all of the land of the district will be restored to its natural level. Instead of the dredge companies sending their earnings away, the Natomas Con. Co. alone is bringing into the Sacramento valley millions of dollars from foreign sources. At present this company is preparing to reclaim tens of thousands of acres in the Sacramento valley, and in a few years they will have populated and made that part of the Sacramento valley which is now a waste, a garden spot in the State.

San Francisco, July 24.

W. B. WINSTON.

The Editor:

Sir—The most noticeable feature of the convention called by the mayor of Sacramento, and held in that city on Wednesday last, to discuss the dredge mining industry and its effect upon the rivers of the State, was the great diversity of opinion among the delegates themselves as to the cause of the present condition of the rivers. The delegates were agreed that the Feather and Sacramento rivers, during extreme high water, have materially damaged farming lands; but, while some of the speakers assumed that the dredging operations were the sole cause of the raised water-plane of the rivers, and the consequent injury to the agricultural interest, no one seemed prepared to assign a particular cause; that is, there seemed to be neither proof nor argument to show whether the dredging operations were the proximate cause of the trouble, or whether natural conditions would have brought the same results. In short, the convention seemed to lack a major premise on which to base a resolution.

Many delegates spoke, but there were as many opinions as there were speakers, some believing that the dredging industry, and nothing else, was responsible for all the resulting damage, and others maintaining the contrary view, even in cases where the speaker had suffered seriously from the overflow. The first real light was thrown on the subject by State Engineer Ellery, who said, in substance, that the main question before the convention, and the one that brought the convention together, could not pos-

sibly be determined until a mass of data, based upon careful observation and measurements of the rivers at various points, had been secured. Capt. Thos. H. Jackson, U. S. A., of the Anti-Débris Commission, stated that the Commission had determined that dredge-mining, excepting in one or two cases, had not done any injury to the channel of the river where it was carried on.

The only business actually transacted by the convention was the appointment of a committee to investigate the subject, to report favorably upon dredges that were operating without injury to the rivers, to expostulate with any dredging company that in the opinion of the committee was doing damage, and if expostulation was of no avail, to call in the aid of the Anti-Débris Association in dealing with the offender. It appeared that if the convention had procured such information in advance it would have had either better cause to convene, or no cause at all.

B. S. NOYES.

San Francisco, July 23.

A New Proposal for Silver.

The Editor:

Sir—Concerning a suggestion made by certain parties in America to "resume the free coinage of silver, collect all duties in gold, place a prohibitory import duty on silver, and secure an agreement with Mexico, Peru, and Bolivia to do likewise," the question arises, could the situation be controlled? I should think so, most decidedly. Does not the tariff create an artificial price on every commodity on which even a small duty is laid? Does not the price of arriving South African gold advance in London whenever the bankers of Paris, Berlin, or any other European financial centre want a part of it, compelling the Bank of England to pay just so much more per ounce if it desires any? Of course it would be advisable to include Canada in such a 'Bund', for that country is now the fourth largest producer of the white metal in the world, having yielded 12,750,000 oz. in 1907, which was exceeded only by Mexico with 65,600,000, United States with 58,850,615, and Australia with 17,516,433, while Bolivia and Peru together produced only 12,000,000 oz. The three principal nations of North America, producing as they do over 70% of the world's annual crop, acting together, could advance the price of the metal to \$1.30 per oz. before a single coin was minted. The United States and Mexico in concert, with their combined output of nearly 65% of the world's total, could do the trick with ease. The United States alone, as it is producing over 30%, could accomplish the rehabilitation of the metal, in my opinion. Who controls the price of wheat all over the world but the farmers of the Mississippi Valley, who produce less than 20% of the world's crop, and have now less than 5% of that total for export? Who makes the international price on cotton but the Texas planter, or of wool but the Australian sheep farmer, or of sugar but the Cuban and Hawaiian producers? Similarly, the American miner would name the market price of silver, if the natural right had not been taken from him by legislation. What would happen to the price

of beet sugar or wool if the congresses of the leading nations should pass laws to the effect that only cane sugar could be used as food, and only cotton as a fabric for clothing, or vice versa?

But would it be wise to attack the problem in the way suggested? That is the real question. I think not. Two wrongs do not make a right. One unnatural step does not warrant another of the same kind as a corrective, even were it possible to make it. It is beyond hope to expect that a Congress perspiring in Washington over tariff rates on toothpicks, buttons, and ladies' hose, would have time to consider other matters of apparently greater importance. Any attempt to secure united action on the part of the three North American nations, or any two of them, would meet innumerable obstacles, and take years of negotiations. England would block Canadian participation, and the large foreign capital interested in Mexican banks would fight desperately for their acquired right to float paper money.

No, the commercial world is deeply in trouble on account of the outcome of the single gold standard, but does not yet appreciate what is the matter, and will not find out by being told, except by their own chosen prophets and wise men, and the latter are scanning the horizon in every direction for a way to re-open the question without drawing down on themselves the imputation of fickleness and inconsistency. It will pay to let them perspire freely for a time. Europe (except France, whose wise financiers practically retained bimetalism, while nominally abandoning it) is in hard straits for metallic money, though it gets the immense South African and Australian output. The United States can afford to stand pat on the problem, having abundant gold resources of their own, and can wait until England, Belgium, Holland, Germany, and Austria learn, through experience, what is the matter with their system. They will never reach this knowledge through argument. The majority of financiers, including the Americans, are obstinate and prejudiced, and poorly informed on the question of money. Any effort on the part of silver producers, or the citizens of silver producing regions, to re-open the subject of the free coinage of silver by legislative action would merely revive the arguments promulgated in the campaign of 1895 in the editorial columns of the urban press.

Apparently all that silver producers can do is to quietly present statistical facts from time to time, without argument and without suggestion of a resumption of free coinage. Of prime importance is the dissemination of a correct knowledge of business conditions and methods of trade in Asia and Latin America, where there are large populations of semi-civilized people on whom we would like to confer some of the blessings of civilization, and who raise a cry of 'murder' and run if shown a gold coin. They have an enormous capacity for the absorption of silver, and will take it at the rate of thousands of tons per annum, and will pay for it in labor and produce, at the old ratio of 16 to 1. We could sell them an unlimited quantity of our manufactured goods. Out-numbering the occidentals three to one, and so far as laborers go, ten to one, the balance of trade always has been in their favor, and always will be until they

reach the Western level of civilization. The trade-balance has always been settled in silver, and it is their preference to continue that arrangement. The West has the silver, and silver mining is one of the most profitable of industries, with the metal at its ancient value. Apart, then, from the money question, it is to the interest of the great commercial nations to look for ways and means to advance the commodity value of silver to the ratio to which the uncommercial nations are prepared to accept it. The opposite plan of cheapening its price, so that the foreign trader could buy it in the market at his own figure, and then make a profit in paying it to the Oriental at the old ratio, has been thoroughly tried out, and has proved to be, like all tricks, of no permanent advantage. The wily Asiatic trader has learned the game, and is now gathering these little profits himself. Meanwhile silver has been so discredited here that the miner is producing it at a loss, or at far less than he should receive, or else as a by-product; and the trader at Hong Kong, Calcutta, Bombay, Singapore, and other Eastern ports is the only man who has gained by our foolishness. He can still pass off the silver on the laborer of the interior for the produce of the land, at or near the old ratio. Again, by making silver mining unprofitable, or nearly so, miners all over the world have turned their attention to gold, and are producing it in such enormous quantities that its purchasing power is declining. We cannot pay our debts in Asia with the yellow metal, and we can only sell a limited amount of our manufactures to the people of that continent, because wages there are so low that a man has to work a week to earn the price of a cotton shirt. That is largely the case because the Westerners have artificially depressed the commodity-value of the metal they employ as money.

In my opinion, the West will never return to free silver coinage, because it is rapidly approaching the point where the free coinage of gold will have to be stopped. Paper money, absolutely devoid of intrinsic value, and based wholly on confidence (national or international, and not individual), is the goal toward which civilization seems swiftly and inevitably tending. When that condition arrives, if silver, as a commodity, stands at its old ratio with gold, it will buy two and a half times as much Eastern raw material and labor as it does now, and will, by just so much, stave off the day when the West will be commercially overwhelmed by the yellow and brown man. But if by then it is still discredited here, nothing is more certain than that all manufacturing will have to succumb to the labor competition of the East.

THEO. F. VAN WAGENEN.

Zacatecas, Mexico, June 30.

Petroleum is being used in Alaska for fuel to such an extent as to seriously interfere with coal consumption. At the Treadwell group of mines petroleum was substituted for coal in 1908, and there was also an increase of petroleum-burning engines on Yukon river boats. The shipments of petroleum to Alaska in the year ending June 30, 1907, amounted to 117,696 bbl.; in the succeeding 12 months they increased to 285,642 barrels.

BEAR RIVER DISTRICT.

Written for the MINING AND SCIENTIFIC PRESS
By W. W. RUSH.

The Bear River mining district, situated at the head of Portland canal, British Columbia, occupies a strip of land about 25 miles long by 5 wide, drained by Bear river. The country is rugged, and but for its proximity to tide-water would be difficult of access. As usual, the Provincial Government is rendering substantial assistance in opening the country. Bear river has been spanned by a 1400-ft. bridge, and

This district lies on the eastern flank of the Coast Range granites, and the mineral deposits occur for the most part in slates, quartzites, and silicious limestones. These latter rocks are often schistose, but the schistosity is not so general or so marked as on the western flank of the granite. Many varieties of igneous rocks occur, but their relation to the ore deposits has not been worked out. No fossils have been found, and any statement made hitherto in regard to the age of mineral deposits is merely speculative. No professional geologist has examined the country thus far, but R. W. Brock, Director of the Canadian Geological Survey, is expected to visit the camp this summer.

Taken as a whole, Bear River is a silver-lead district, but copper and gold are also found in paying quantities. The Red Cliff, situated on American creek, 15 miles up Bear river, is a notable exception to the ordinary type of mineral deposit of the camp. This property presents features analogous to the famous Mt. Morgan mine. It is a big irregular deposit of iron and copper-iron sulphide, with primary gold. Five miles farther up American creek is the Stewart-Brightwell property, one of the first located in the district. Here is a big silicious outcrop containing native silver and silver as chloride, and in combination with sulphur. The absence of pyrite and iron-stains is noticeable. By far the greatest amount of prospecting and development has been done on Glacier creek, from 6 to 10 miles from tidewater. Practically all of the creek is staked, and there are few claims without well defined quartz lodes and some ore. On this creek is a series of blanket veins following parallel bands of slate. Pyrite, galena, zinc-blende, chalcopryite, argentite, and native silver are present in a gangue of quartz. Varying amounts of gold are also found. Other veins cut the formation at various angles, and contain silver associated with pyrite, arsenopyrite, blende, galena, stibnite, and a dark sulphide of varying composition, usually called 'gray copper'. These minerals occur in a gangue of quartz, barite, and silicified rock. The Griffith-McGrath lode affords the most conspicuous example of the first-described class of veins. It is a strong vein, and very persistent in its strike. The Portland Canal Mining Co., operating on this vein, will spend

Map Showing Location of Portland Canal.

every year sees an extension of the system of roads and trails.

From Bear river a panoramic view of the country may be obtained. On either side rise precipitous walls of gray granite, iron-stained schists, or gentler slopes covered to an altitude of 3000 ft. with a thick growth of hemlock, spruce, and balsam. Snow and ice crown the higher peaks, and noisy torrents thread their sides with silver. Mines and prospects occur from sea-level to an altitude of 4000 ft. Owing to the moderate elevation, and the influence of the sea, the winters are probably less severe than in many mining districts of the States.

\$100,000 this summer in development and equipment, including an aerial tramway and concentrator.

The first prospecting of any consequence in the district was done in 1898 by a division of the army of gold-seekers which that year ascended every river and inlet of the Alaskan and British Columbian coast. Placer gold in paying quantities was not found, but interest in the base-metal deposits was aroused, and the first lode-locations were made. In 1905 many prospectors were attracted to the district by reports of the Stewart-Brightwell discovery, and as a result of their explorations Glacier creek was opened up.

PETROLEUM FIELDS OF ILLINOIS.

Written for the MINING AND SCIENTIFIC PRESS
By H. FOSTER BAIN.

Since June 1905 Illinois has produced approximately 85,000,000 bbl. of petroleum, and current production amounts to over a quarter of a million barrels per month. Prior to that date the State had been only an insignificant and infrequent producer. Following each of the great Eastern oil excitements, 'wild-cat' wells had been put down, and limited amounts of gas and oil had been found at a number of points. Near Litchfield, in Montgomery county, a small field was developed in 1886 and continued producing up to 1902, with a total output of 6000 bbl. At Sparta, in Randolph county, gas was found in 1888, and was used for some years. By 1904, however, production ceased, and when J. J. Hoblitzel began drilling near the old gas wells struck in 1865

Eastern Illinois Oilfield.

in Clark county, it was the general opinion that Illinois was 'not in the oil belt'. His success near Casey led to rapid development through Clark, Cumberland, Coles, Crawford, and Lawrence counties, and in a remarkably short time after shipments began, one of the world's great oilfields was outlined.

The productive territory as now known extends from Westfield, in Clark county, approximately 80 miles in a direction a little east of south, and averages from 10 to 16 miles in width. The field is in southeastern Illinois, and the main production comes from Clark, Crawford, and Lawrence counties, the three shaded on the accompanying map. On the larger map the productive territory is shown in greater detail.

Some eight or ten separate pools are recognized. At the extreme north of the field, extending from Westfield to Oilfield, is the first pool discovered. Connected with it geographically, and extending south about six miles, is the Casey township or Martinsville pool, which in turn connects with the John-

son township pool to the south. Detached and extending to the west in Cumberland county is the Siggins pool. In Crawford county, west of Robinson, is the extensive Robinson or Oblong pool. Southeast of Duncanville is a small pool taking its name from this town. Southwest of Flat Rock is the Honey Creek pool, while southeast of the same town is the Birds pool. In Lawrence county there is the big Bridgeport pool, though here, as in several of the others, different sands are recognized in various parts of the area.

The depth of the wells generally increases consistently from north to south. In the Oilfield pool the sand lies 300 to 350 ft. below the surface. In the Siggins pool there are two sands found approximately 400 and 570 ft., respectively, in depth. In Johnson township, again, there are two sands, lying 470 and 610 ft. below the surface. In Crawford county there seems to be a group of sands lying 900 to 1000 ft. deep. Frequently two are developed in one hole. In Lawrence county there are three sands, the Bridgeport of 950, the Buchanan at 1300, and the Kirkwood at 1500 ft. The country is very flat, so that while the topography affects the depths slightly, the main differences are due to structural features of the rock.

All of the oil comes from Carboniferous formations. With the exception of the Kirkwood, which is found in the Chester formation of the Mississippian, the sands occur in the Pennsylvania rocks. The latter have not yet been studied in Illinois in sufficient detail to permit of the series being broken up into formations which may be certainly correlated from place to place. It is known that at the base of the series is a variable thickness of Pottsville rocks, mainly conglomerates, sandstones, and sandy shales. In this division the Buchanan sand occurs. The Bridgeport, Robinson, and Duncanville sands, all lying at about the same horizon, belong either in the top of the Pottsville or the base of the overlying coal measures. Owing to imperfections of data, it is impossible as yet to make certain to which they should be referred. The remaining sands are all in the coal measures, presumably not extending far into the upper division. In the southern pools, higher sands, corresponding at least approximately to the productive sands of the northern pools, are frequently discovered. They often show small amounts of gas, but very little oil. In the northern district a few deep holes have been put down, and some at least are reliably reported to have yielded a little oil. Deep exploration has not, however, been systematic, and most of the results have been unfavorable. Sufficient data are not at hand to trace northward the deeper productive sands.

The field is situated along the line of strike of the La Salle anticline, a marked feature of the geological structure of the State. The productive pools are all under this upward bend of the strata, but the arch here is broad and low, and local distribution of dry and productive territory is erratic. To some extent the occurrence of the oil seems to be controlled by minor arches, but porosity of rock and irregular distribution of salt water evidently enter into the problem also. Pending the completion of detailed studies now being made by the State Geological Survey, it

is impossible to give a complete explanation of the occurrence of the oil.

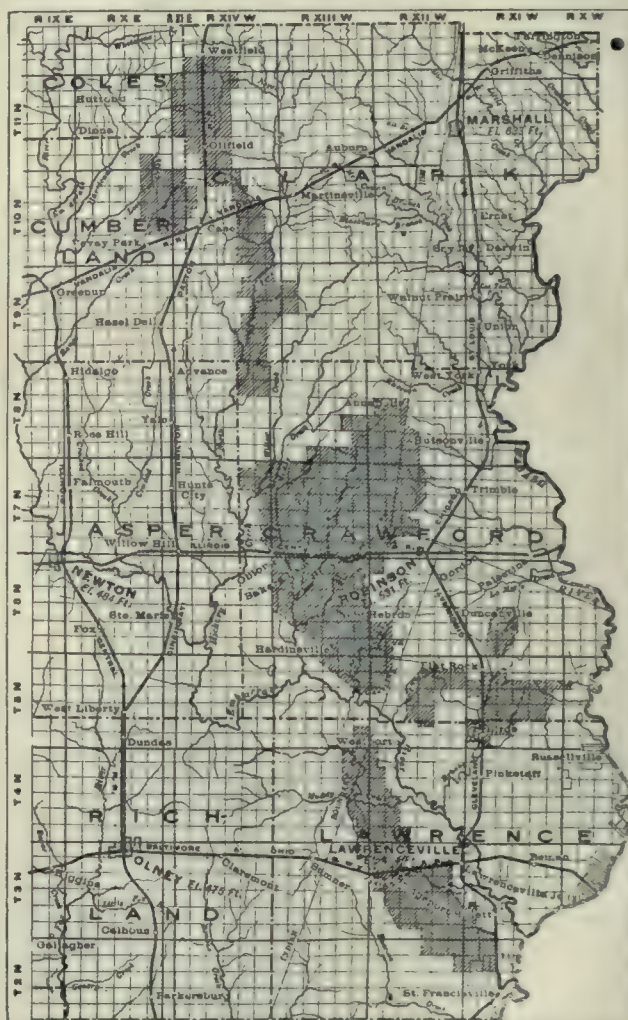

The amount of gas found is not large. In general it has not been more than enough to do the work of drilling and pumping and supply the farmers and local towns. Between the Flat Rock and Honey Creek oil pools, good gas wells occur, and show 80 lb. pressure after two years use. The gas from this field is piped north and south, but west of that place gas occurs with the oil, and is commonly wasted.

Outside of southeastern Illinois, and excluding gas found in the drift, petroleum and natural gas have been noted at a number of points in the State. On the west, from Sparta in Randolph to Litchfield in Montgomery county, both gas and oil have been found. From Sparta oil is now shipped in small quantities. Traces of oil have been found at Shipman, Smithton, Hillsboro, and other points. In this territory there is a pronounced erosion unconformity, both the Pottsville and Chester being cut out over parts of the territory. These beds also become thin to the north, but all the oil so far found has been in them or in the coal measures, as in eastern Illinois. As they show the same lithology as in the latter area, and as there are anticlines in western as in eastern Illinois, these showings of gas and oil are considered to be significant of probably larger quantities to be found by further prospecting. In southern Illinois the rocks are much disturbed, faulting as well as folding being fairly widespread. For this reason the conditions are not considered equally favorable, though very little prospecting has been done in the beds most likely to be productive. Some small amounts of gas and oil have been found in the coal measures.

Outside the area covered by the Pennsylvania rocks little is known of the possible presence of gas and oil. Neither has been found in the Mississippian below the Chester. The Devonian is not widespread in Illinois, and shows no evidence of the presence of either. The Niagara and the Galena-Trenton are widely present, are coarse thick dolomites, well adapted to the storage of petroleum, are covered by suitable shales, and both show more or less oil seepage where they outcrop. In addition, there is a small but attractive gas-field in Pike county, where the Niagara is brought near the surface by a minor anticline. In La Salle county a small amount of gas has been obtained from the Trenton. In the drift, gas is obtained at a number of points. While these wells seem, in certain cases at least, to derive their supply from decaying vegetation in the drift, the hypothesis of leakage from lower reservoirs cannot be entirely excluded. An interesting feature of these wells is the occasional finding of one which yields nitrogen instead of the ordinary combustible gas.

In contrast with the oil territory of California, with its mountains and rocky bluffs, Illinois is a flat, drift-covered plain. The rocks outcrop at only a few points. The geology can only be learned by study of drill records. On this account the first prospecting in each district is necessarily blind, but with the records now available, important aid may be derived from geology. In another particular also there is striking contrast. In Illinois there is no public land.

The country is all settled, and either cultivated or devoted to pasture. The oil-men deal entirely with individual owners, and oil-leases are private bargains. There are almost no special laws or regulations, as in the Western States. While some of the territory is developed by fee owners, it is in most cases leased from the owner for a term of five years, or as much longer as production continues. If the neighboring farms are untested, the owner usually gets from one-eighth to one-sixth of the oil as royalty. There is commonly an agreement that the drilling is to begin within a year or less, or that a stated rental per acre shall be paid till the first well is drilled. The land-owner retains all rights to the surface of the ground, except for the portion necessarily

Oil Pools in Eastern Illinois.

occupied by derricks, power-houses, and ordinary storage-tanks. If large storage is to be provided, it is customary to buy the land for the tank-farm outright. The local courts have interpreted rather strictly what surface land is necessary to production, but in many cases, since for agricultural purposes the land is only worth approximately \$30 per acre, much of the surface lies idle during production, and the oil-men use as much as they like. On a farm of 80 acres not more than 5 is necessarily kept from cultivation.

If oil has already been found on adjacent territory, a bonus is in order, and the farmer receives from \$30 to \$200 per acre in addition to the royalty and his reservation of the fee. When oil is developed the lease becomes the most valuable part of the oil

property, and is often sold. The price realized depends on many factors, but mainly upon the number of wells producing and on their average daily yield. There is a steady market for producing leases, and much trading even in those which are unproductive.

Wells are put down 400 to 600 ft. apart, beginning usually 200 ft. back from the boundary line. A well

of companies. Development has from the first been in the hands of experienced and capable oil-men, and the work has been done with that quiet efficiency which it is the joy of technical men to see.

The wells are not large, as judged by Western standards. In 1908, 3574 wells were completed, of which 555 were dry holes. The new production is given as 77,413 bbl. The Casey pool, after four years production, yields approximately 6 bbl. per well. The Crawford county wells, at the beginning of the fourth year of production, are yielding about 20 bbl. each. The Lawrence county wells are most productive, and give an average of about 40 barrels.

The amount won per acre is variable. Some of the territory has yielded 4000 bbl., and is still producing. Other wells, which looked equally good when bought, yielded only 500 bbl. per acre. One tract produced 8000 bbl. per acre, and from another tract of 20 acres over a million barrels of oil were taken. The last was only possible because the owner built his own storage-tanks and pumped constantly. Since the pipe-lines are only able to take from 50 to 75% of the oil offered at any one time, it is evident that this

understood rule requires immediate drilling when oil is struck on adjacent territory, and any attempt to drill close to the line is promptly met by competing wells just over the fence. As a result, this 'bucking the line' is unprofitable, and is considered distinctly bad form by all good oil-men. A common arrangement provides for 14 wells on 80 acres, protecting all sides and leaving 920 ft. clear in the centre.

Ordinary standard rigs are now used in drilling, though many of the shallow wells in the northern part of the field were put down with masts. The rigs are built 72 ft. high. The wells are cased and shot, and are provided with the usual 250-bbl. wooden storage tanks, as many as the operator can afford. They are pumped by jacks operated by gas-engines. From a dozen to 30 wells are connected by rods to a single engine, and one pump-man cares for the lease. The cost of production is small, and the cost of drilling has also been unusually low. In Clark county wells were put down for as little as \$1000. In Crawford the cost ran up to \$2500 to \$3000, and in Lawrence the deeper wells (1800 to 2000 ft.) cost approximately \$5000 each. Many wells have flowed enough oil to pay for themselves by the time they are connected with field lines, and in general the field has been one where many men have made money and few have lost. It has been fortunate in that there was never a 'boom', with the corresponding flotation of stocks by men experienced only in the promotion

enterprising gentleman got some oil which would have gone to his neighbors had they been similarly provided with storage.

The Ohio Oil Co., with F. G. Hillman manager and J. F. Kerr superintendent, represents the Standard,

Standard Rig for Drilling.

and buys over 90% of the oil. It also owns and operates leases, and is a steady buyer of producing territory. How much of the production comes from its own leases is not known, but certainly less than half. Four pipe-lines to the East, and one to Alton, on the Mississippi, with storage tanks for over 25,000,000 bbl., have been built, in an effort to take care of the production. Even at this it has never been possible

for more than two weeks to take all the oil offered. In pro-rating, the company treats its own leases exactly as it does those of its competitors. Outsiders claim that its continued drilling compels them to bring in new wells in self-defense, and the reverse claim is made by the company. Probably human nature keeps both at work.

Within the field the oil is collected by a gravity system built by E. C. Bolton, chief engineer, with pumping stations at Oblong, Bridgeport, and Martinsville. The oil is pumped at 600-lb. pressure, and goes from Martinsville to Alton without relays. The oil is not as viscous as that produced in California, and an 8-in. line handles about 300 bbl. per hour. This amount can be increased by adding to the pumping plant, and varies about 10% with the seasonal changes of temperature. In 1908 the pipe-line runs of this company amounted to 31,972,630 barrels.

In the same period independent refiners shipped 1,523,648 bbl. Up to the present the independents have been forced to rely on tank-cars for shipments, or to sell to the Standard. Most of them have preferred the latter plan. The Tidewater Oil Co., however, has recently built a 6-in. line into the field, and it is estimated now that the independents are handling 10,000 to 15,000 bbl., and that they may be able to care for 25,000 bbl. per day by the close of the year. The Pure Oil Co., which is a large producer in this field, is said to have bought right of way for a second independent pipe-line. The Indian Oil Refining Co. has 500 tank-cars and 30 distributing stations, with refineries at Georgetown, Ky.; Lawrenceville and East St. Louis, Ill.; with a combined capacity of 6000 bbl. per day. The Sun Oil Co. ships by tank-cars, selling its oil for fuel. The Central Oil Co. maintains a refinery at St. Louis, Mo., while the Cornplanter and the Robinson Oil Refining Co. maintain small plants in the district.

While the independent refiners are undoubtedly doing well, the Ohio still dominates the field, and in June reported pipe-line runs of 2,365,956 barrels.

The oil ordinarily runs from 30 to 35° B. That from the Duncanville pool is 22 to 23° B, and is sold only for fuel. Aside from this, little oil is sold except to the refineries. In the surrounding territory coal is cheap and abundant, so that it is not necessary to sacrifice the oil by using it under boilers. The oil is low in sulphur, and sells at 68c. for that above 30° B gravity, and 60c. for that below. At these figures there has been a large profit, and the owners of 'crayfish land' elsewhere in the Mississippi Valley will extend a warm welcome to anyone desiring to locate further 'wild-cats'.

Oil is found for a distance of 250 miles on the eastern coast of Saghalin, but it is yet to be proved whether or not this oil belt can be developed so as to be of commercial value. As the oil is found so near the seacoast, it could readily be transported. It should therefore be an inviting field for development, and if all the rumors are to be believed, great activity in such development will be shown during the coming spring and summer.

Tin is being developed at Hainan in China.

FAIRBANKS GOLD REGION, ALASKA.

The decrease in the production of gold in Alaska in 1907 and 1908 does not mean, in the opinion of the United States Geological Survey, that the gold of the region is approaching exhaustion. It resulted partly from labor troubles and partly from lack of water for gold washing. Despite these drawbacks, the Fairbanks region, which produces nearly half of all the gold of Alaska, yielded about \$9,200,000—slightly in excess of its former maximum output. The region has progressed materially, and preparation has been made insuring a large production in the near future. The Tanana Valley railway, a narrow-gauge road about 50 miles long, was in 1907 finished to Chatanika, at the mouth of Cleary creek, and wagon-road improvement and construction had so far advanced by the close of the season of 1908 that heavy loads could be conveniently laid down at the workings on almost all the creeks of present importance. Through these means the high freight rates formerly prevalent have been reduced to a few cents per pound for summer freights to the most extreme points. The region has been in communication with the outside world by means of the Government telegraph system for several years, and during 1908 additional service was rendered available by the successful installation at Fairbanks of a wireless station operated by the Government. At Fairbanks foundries and machine shops, excellently equipped and under the direction of good mechanics, have been established. Much machinery especially adapted to the mining conditions prevailing in the district has been devised and entirely constructed in these local shops. Freight and passenger rates from Seattle to Fairbanks remain about the same, averaging in 1908 about \$75 per ton on ordinary supplies and \$125 to \$140 for first-class passengers.

An experiment in winter work promises very well for the future. The weather permits ordinary sluicing, at the most, for 150 days. An attempt at winter-slueicing was made, however, in 1907-8, on Esther creek, where water was warmed by the exhaust from the hoisting and pumping engines and pumped to the sluice-boxes. Sluicing was continued into January. As a result of this experiment several operators are preparing for winter sluicing during 1909.

Deep mining in Victoria involves attention to ventilation. In order to carry on economical mining it is necessary to have as large a volume of air circulating through the workings as possible. For instance, at 4254 ft. the rock temperature, 113.5°, and the water, at 114° F., requires a volume of natural air of not less than 10,000 cu. ft. per min. to maintain a temperature of 72 to 75°. The temperatures vary from summer to winter. In driving dead ends a system of overhead bratticing has been introduced to keep a current of air circulating to the face. A volume of 1250 cu. ft. is required in one mine to maintain a temperature of 86°. This system is the best yet developed for deep ground. Blowers have been tried, with poor results, the ground being so hot the pipes acted as conductors and made the air too hot in a distance of 400 ft. They have been found to heat the air 10 degrees.

VELOCITY OF FLOW OF WATER IN PIPES.

Written for the MINING AND SCIENTIFIC PRESS
By LEONARD M. GREEN.

The velocity of flow of water in a pipe under a given head may be quite closely calculated by a formula, when the pipe is of considerable length, but the available formulae do not give satisfactory results when the pipe is short and when the entry-head has to be taken into account. If there were no friction in the pipes, and no loss of head due to entry, then the velocity of flow in feet per second would be $\sqrt{2gh}$, where g is the acceleration in feet per second, due to gravity, namely, 32.16, and h is the total head in feet of water producing the flow.

The velocity of flow from a plain circular orifice is only about 62% of the theoretical velocity, namely, $0.62 \sqrt{2gh}$, and it therefore corresponds to a theoretical head of

$$\left(\frac{0.62 \sqrt{2gh}}{2g} \right)^2 = 0.385 h.$$

The loss of head due to entry is therefore 0.615 h , or 61.5%. By attaching a short piece of circular pipe equal in length to twice the diameter of the orifice, and of a diameter equal to the orifice (a cylindrical nozzle), the velocity of outflow may be increased to 82% of the theoretical, that is, to $0.82 \sqrt{2gh}$. This corresponds to a theoretical head of $\left(\frac{0.82 \sqrt{2gh}}{2g} \right)^2 = 0.672 h$. In this case, therefore, the loss of head due to entry is 0.328 h , or 32.8%. In most cases of flow of water in pipes the loss of head may be considered as being due to the entry-loss caused by a cylindrical nozzle such as that above mentioned, plus the loss occasioned by an additional length of pipe, the total head being the difference of level between the upper surface of the water in the vessel from which the flow takes place, and the level at which the water is discharged. If the flow be caused by pressure, the head in feet of water is equivalent to the pressure in pounds per square inch $\times 2.309$. The actual velocity is therefore that which would be theoretically produced by a head equal to the total head minus the friction-head caused by the total length of pipe, less a length equal to twice the diameter, minus the head lost by entry, including a length of pipe equal to twice the diameter.

Let v feet per second equal the actual velocity produced by a total head of h feet in a pipe of a diameter d inches, and of a length of 1 foot. Let F equal the friction-head per foot of pipe at the velocity of v feet per second.

Let l_e equal the number of feet of pipe of a diameter d inches, producing a friction-head equivalent to the entry-head when the velocity is v feet per second.

Then the theoretical head-producing flow equals total head minus pipe friction-head minus entry-head. This is equal to

$$h - F \left\{ \left(1 - \frac{d}{8} \right) + l_e \right\}$$

and therefore the actual velocity v equals

$$\sqrt{2g \left[h - F \left\{ \left(1 - \frac{d}{8} \right) + l_e \right\} \right]} \quad \text{Equation 1.}$$

Let f equal the friction-head per foot of pipe of 1 in. diam. at a velocity of 1 ft. per second. Then,

since the friction is proportional to the square of the velocity, the friction-head per foot of 1 in. diam. pipe at a velocity of v feet per second is $v^2 f$. For any other diameter the friction-head per foot of length will vary as some function of the diameter. In tables published by the Pelton Water Wheel Co., based on Cox's formula, the friction-head varies inversely as the diameter, but it would seem more probable that it should vary inversely as some power of the diameter greater than 1, and the results of Ellis and Howland's experiments, and the friction-heads as calculated from D'Arcy's formula for rate of flow, show that this is the case. The friction-heads per foot of pipe at a velocity of 2 ft. per second for pipes of various diameters as given by Ellis and Howland, Cox, and D'Arcy are shown below, and the results have been averaged.

| Diameters of pipe in inches. | | | | | | |
|--------------------------------|--------|---------|---------|---------|----------|----------|
| 0.5 | 1 | 3 | 6 | 12 | 24 | 48 |
| Velocities in feet per second. | | | | | | |
| | About | 0.0097 | 0.0032 | 0.0015 | 0.00065 | 0.00030 |
| | 0.0350 | 0.00791 | 0.00395 | 0.00198 | 0.00098 | |
| 0.0854 | 0.0297 | 0.0066 | 0.00286 | 0.00136 | 0.00065 | 0.00031 |
| 0.0854 | 0.0295 | 0.00807 | 0.00334 | 0.00161 | 0.00076 | 0.000305 |
| $\frac{1}{d^{1.2}}$ | | | | | | |
| 0.0730 | 0.0317 | 0.00848 | 0.00369 | 0.00162 | 0.000702 | 0.000305 |

If the friction head for the 48-in. pipe at a velocity of 2 ft. per second be taken as 0.000305, and the head be made to vary as $\frac{1}{d^{1.2}}$ where d is the diameter of the pipe, a set of figures is obtained which agrees fairly well with the average. Corrected for a velocity of 1 ft. per second, the figures for the friction-head are:

| 0.5 in. | 1 | 3 | 6 | 12 | 24 | 48 |
|---------|--------|---------|---------|---------|----------|----------|
| 0.0182 | 0.0079 | 0.00212 | 0.00092 | 0.00040 | 0.000175 | 0.000076 |

Therefore f (the friction-head of 1 ft. of 1-in. pipe at a velocity of 1 ft. per second) may be taken as 0.0079.

$$\text{Then } F \text{ (in Equation 1)} = \frac{f v^2}{d^{1.2}} = \frac{0.0079 v^2}{d^{1.2}}$$

The value of f , 0.0079, is for clean cast-iron pipes; for other materials it would of course vary according to the rugosity of the surface.

To find the entry-head, we here consider it to be that due to a short cylindrical pipe or nozzle in length twice its diameter. It has an ordinary plain straight-cut entry to the reservoir, and is not flared or rounded. For simplicity the head may be taken as being equivalent to a certain number of feet of pipe. For a 1 in. diam. pipe of 2-in. length the velocity of flow due to a head of h feet will be 82% of $\sqrt{2gh} = 6.576 \sqrt{h}$ ft. per second. This is theoretically due to a head of $\frac{(6.576)^2 h}{64.32}$ feet, or to 0.6724 h feet. The loss of head due to entry is therefore 0.3276 h feet. This would be equivalent to the friction-head produced by $\frac{0.3276 h}{f}$ feet of pipe at a velocity of 1 ft. per second, but as the velocity is $6.576 \sqrt{h}$ feet per second, it is actually equivalent to $\frac{0.3276 h}{f} \times \frac{1}{(6.576 \sqrt{h})^2}$ feet of pipe = $\frac{0.00757}{f}$ feet of pipe.

For pipe of any other diameter d it will be equivalent to $\frac{0.00757 d^{1.2}}{f}$ feet of pipe.

$$\text{Therefore } l_e \text{, in Equation 1,} = \frac{0.00757 d^{1.2}}{f}$$

For clean cast-iron pipes, $f = 0.0079$, so that the

entry-head is equivalent to 0.96 ft. of pipe of 1 in. diam., or $0.96 \times d^{1.2}$ feet of pipe of diameter d.

Substituting the values of $F \left(\frac{f v^2}{d^{1.2}} \right)$ and of $l_e \left(\frac{0.00757 d^{1.2}}{f} \right)$ in Equation 1, we obtain

$$v = \sqrt{2gh - 2g \frac{f v^2}{d^{1.2}} \left\{ \left(1 - \frac{d}{6}\right) + \frac{0.00757 d^{1.2}}{f} \right\}}$$

Therefore

$$v^2 = 2gh - v^2 \left\{ \frac{2gf \left(1 - \frac{d}{6}\right) + 2g \times 0.00757 d^{1.2}}{d^{1.2}} \right\}$$

$$v^2 = \frac{2gh d^{1.2}}{d^{1.2} + 2gf \left(1 - \frac{d}{6}\right) + 2g \times 0.00757 d^{1.2}}$$

or
$$v = \sqrt{\frac{64.32 h d^{1.2}}{1.487 d^{1.2} + 64.32 f \left(1 - \frac{d}{6}\right)}} \qquad \text{Equation 2.}$$

For clean cast-iron pipes, $f = 0.0079$,

so that
$$v = \sqrt{\frac{64.32 h d^{1.2}}{1.487 d^{1.2} + 0.508 \left(1 - \frac{d}{6}\right)}}$$

The above formula may be used for any length of pipe and for any head. The results obtained by this formula on some sizes of pipes with different heads are compared in the following table with those calculated by D'Arcy and Cox's formulae, and with some figures given by Kuichling. The latter figures are given for pipes of nominal diametres; the other columns are for actual diametres.

| | | Velocity in feet per second— | | | | |
|-----------------------|---------------------------|------------------------------|--------|-------|-----------|---|
| Diameter pipe, inches | Head, feet | Length, feet | D'Arcy | Cox | Kuichling | Actual velocity |
| | | | | | | from pipe of length twice the diameter. |

It will be noticed that for fairly short lengths of pipe the results given by D'Arcy's formula are much too high for the larger diameter pipes, being sometimes three or four times more than the maximum flow that can be obtained from the pipe. It is therefore evident that D'Arcy's formula can only be successfully used for considerable lengths of pipe, for short lengths give results which are entirely misleading. The same applies to Cox's formula. The proposed formula, on the other hand, gives results which are apparently approximately correct for the flow of water in pipes of any diameter and under any variations of length and head, with the exception, of course, of the flow in capillary tubes. For pipes of other material than cast-iron the factor f (0.0079) must of course be altered to suit the rugosity of the surface. If the pipe where it enters the reservoir is cone-shaped or flared, the entry-head may be equivalent to as little as $\frac{0.00275}{f}$ feet of pipe. This causes the factor by which $d^{1.2}$ is multiplied in the denominator (namely, 1.487) to become 1.177. If the entry-head be entirely neglected the factor becomes 1.000. The value of $d^{1.2}$ for several diameters is given below. For any particular value of d the value of $d^{1.2}$ can be readily obtained from a table of logarithms.

| | | | | | | | | |
|-------------|-------|------|------|------|------|------|------|------|
| Diam. d in. | 0.5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| $d^{1.2}$ | 0.435 | 1.0 | 2.3 | 3.74 | 5.29 | 6.90 | 8.59 | 10.3 |
| Diam. d in. | 8 | 9 | 10 | 11 | 12 | 24 | 48 | |
| $d^{1.2}$ | 12.2 | 14.0 | 15.9 | 17.8 | 19.6 | 45.2 | 104 | |

Coal was first noted in the Coos Bay region of Oregon about fifty years ago, J. S. Newberry having reported in 1855 that they had begun to attract attention. It is known that some mining was done there in 1855 and in 1872, and that in 1876 two mines—the Eastport and the Newport—were in active operation. The Newport mine, however, was the only one to survive. The Beaver Hill mine was opened in 1895 and is now one of the important producers. The first record of coal production from this field is contained in the census report of 1880, which shows that in that year 43,205 short tons were mined. The production has exceeded 100,000 tons in four years only—1896, 1897, 1904, and 1905—the maximum, in 1904, reaching 111,540 short tons. The total production to the close of 1908 has amounted to 1,876,651 short tons.

CYANIDATION OF SILVER ORES.

Written for the MINING AND SCIENTIFIC PRESS
By THEO. P. HOLT.

Since the publication of some laboratory experiments on the above problem in the MINING AND SCIENTIFIC PRESS of April 17, I have received a number of personal inquiries regarding the work, which would seem to warrant the submitting of more complete data. The general scope of the work, and also the method of conducting the tests, are discussed in the previous article. As far as practicable I have endeavored to secure uniform conditions in the experiments from which the graphs have been constructed. The required weight of the silver mineral was in each case crushed with a little quartz sand,

due to the power of BrCy as an oxidizer. The bromo-cyanide used in these experiments was made by adding liquid bromine to a 0.5% KCy solution. The solution was kept cold by surrounding the flask with snow. When all the potassium cyanide has been converted into bromo-cyanide a permanent yellow color appears. The strength of solution in BrCy is determined by titrating with a standard thio-sulphate solution. The absence of free cyanide may be assured by a drop of the silver nitrate standard.

A striking illustration of the difference of solubility of gold and silver in BrCy is presented by some results on sample No. 13 (see Fig. 5 and 6). This is a hard quartz-rhyolite from Mexico, assaying 1.29 oz. gold and 56.80 oz. silver. The silver is nearly all present as argentite. Although this ore contained

Fig. 1.

and passed frequently over a 100-mesh screen. It was then mixed with a sufficient quantity of pure quartz sand to make an 'ore' assaying approximately 50 oz. silver. This method of preparation favors the production of a large number of particles approaching the size of the maximum grain, which will in a measure offset the fact that none of the mineral is encased in the gangue. No doubt the surface of mineral exposed to the action of the cyanide solution is much less than obtains in modern slime-treatment practice.

Some statements have been made recently concerning the adaptation of bromo-cyanide to the treatment of silver ores. I find that in the absence of free cyanide it is not a solvent for the silver minerals. However, the addition of a limited quantity of bromo-cyanide to a cyanide solution is often quite efficient in increasing the extraction. This is doubtless largely

Fig. 2.

over forty times as much silver as gold, upon treatment with bromo-cyanide about one third of the gold passed into solution, while not so much as a trace of dissolved silver could be detected. It is also remarkable how closely its silver content follows the line for argentite through the variations in treatment.

With certain of the silver minerals a chloridizing roast seems the only means of securing a satisfactory extraction. The graphic results were obtained on small samples mixed with 5% salt and roasted in an open muffle for one hour. A similar sample, without the addition of salt, was roasted at the same time. The temperature was taken every 20 minutes, and averaged above 700° C. It is evident from the graphs that a chloridizing roast is about equally effective in all cases, the silver being converted into a chloride which is very readily dissolved. It is probable that both the amount of salt and the time of the roast

Fig. 3.

Fig. 5.

Fig. 4.

Fig. 6.

could be materially decreased without reducing the extraction. For an oxidizing roast one hour is too brief a period to materially change the state of the silver.

Variations in treatment reveal some remarkable contrasts in the action of native silver and argentite. Louis Janin, Jr., published the first experimental results on the solution of silver sulphide and cement-

silver in potassium cyanide.¹ He sums up this investigation by stating that "The extraction with silver sulphide is directly proportional to the strength of solution, and with cement-silver inversely proportional." With slight correction the data of his tables are given graphically in Fig. 8. A few years later these 'curious phenomena' were satisfactorily explained by J. S. MacLaurin when he established the fact that "The solubility of oxygen is greater in a weak than in a strong solution, and the amount of gold (or native silver) dissolved is proportional to the absorption coefficients of oxygen."²

A clear knowledge of the fundamental laws of

case is high. The oxygen of the air may be replaced by the various oxidizers, or any electro-negative ion, as OH, Cl, or Br. Thorough aeration seems preferable to the introduction of special oxidizers.

The solution of argentite (Ag_2S) has been discussed recently by a number of writers in the MINING AND SCIENTIFIC PRESS. The primary reaction may be written:

This equation is reversible and incomplete, and owing to the fact that Ag_2S is so slightly soluble, proceeds only to a limited extent before equilibrium becomes established. Unlike the case on native silver previously discussed, the formation of the complex AgCy_2 ion does not remove a sufficient number of the argent-ions to bring any considerable amount of the silver sulphide into solution. The ionic equilibrium existing in the above equation, as it effects silver sulphide, may be represented as follows:

According to the law of mass action, we can cause the above equation to pass in the desired direction by removing either the silver ion or the sulphur ion from the solution. Both methods are practicable.

The silver ions present in a potassium argentocyanide solution are due to the third step in the dissociation of this salt.

If no other salt dissociating either Ag or Cy ions be present in the above solution, the number of these ions is equal; but suppose an excess of KCy is added to the above solution: the result then is that the equality of (3) is disturbed, since the number of Cy ions has been increased, and the silver ions must combine with Cy ions to form undissociated $\text{AgCy} \rightleftharpoons$. Thus the silver ions present may be reduced to an infinitesimal number, and the solution of silver sulphide be allowed to proceed. This end is realized in practice by the use of strong solutions.

The removal of sulphur ions resulting from the solution of silver sulphide and other sources, is brought about by oxidation and precipitation as insoluble sulphides. The degree to which chemical salts are capable of influencing the amount of silver dissolved may be appreciated when we inspect the graphic results of a few tests. (See Fig. 4, 5, 6, and 7.) Take the line for argentite as an example. The 0.5% KCy solution dissolves 38% in 17 hours. The addition of 0.3% lime brings this up to 58%. By making the solution strongly alkaline with KOH, almost 97% of the silver is dissolved in the same time. A small amount (0.2%) of litharge is about equally effective. Litharge (PbO), although it enters the solution as a plumbite, still dissociates a sufficient number of Pb ions to effectively remove the S ions as insoluble PbS . Thus the presence of lead salts prevents the equilibrium indicated above being established, and the solution of silver sulphide proceeds. Any metal, the sulphide of which is but slightly soluble in cyanide solution, will produce a similar effect.

The increased extraction observed on adding potas-

Figs. 7 and 8.

chemistry is essential to a correct interpretation of the experimental results. The theory involved in the solution of gold in potassium cyanide is discussed at length by S. B. Christy in his article on the 'Electromotive Force of the Metals.'³ A summary of these principles in their application to silver is roughly as follows: there are two forces tending to drive the metal into solution: (1) the electromotive force of the silver in a cyanide solution, and (2) the ionizing tendency of the oxygen present. The electromotive force of the metal is the difference between its 'solution pressure' and the 'osmotic pressure' of its ions already present in the solution. But since the compound KAgCy_2 in solution dissociates extremely few silver ions, the electromotive force of silver in this

¹Eng. & Min. Jour., Dec. 29, 1885

²Jour. Chem. Soc., Vol. 63, p. 724, and Vol. 67, p. 199.

³Trans. Amer. Inst. Min. Eng., Vol. 30, p. 864.

sium hydroxide to the solution is also in accordance with the mass law. In this case we have:

Upon adding a highly dissociated salt, as KOH, we greatly increase the number of K ions, and hence the product on the right of the equation. To establish ionic equilibrium some of the K ions must unite with S ions to form undissociated K_2S , and thus effectively removing S ions from the solution. From a practical standpoint the use of some metal to precipitate the sulphur in an insoluble form is much to be preferred, as any other method results in the fouling of the solution, by the accumulation of soluble sulphides.

I trust that this review of some of the fundamental principles of chemistry may be useful in the study of the experimental data. The reactions involved in most cases are complex, and only those which are quite elementary are indicated. I shall be pleased to receive suggestions or criticisms along the line of this work, and hope that further investigation may develop points of practical value for application in the process.

MINERALS IN URUGUAY.

In Uruguay, gold has been found in the Departments of Minas, Treinta y Tres, Montevideo, and Rivera, in placers and in quartz veins. There are but two mines operated to any extent, from which were produced in 1908, 20,514 tons, yielding 2709 oz. gold, valued at \$46,586. Coal is being mined in the Departments of Montevideo, Santa Lucia, and Cerro Largo, while peat exists in Maldonado and Montevideo. The Cerro Largo and Santa Lucia coal is of good quality and will soon be placed upon the local market. Petroleum is known to exist; antimony is found in Santa Lucia, Minas; graphite at Carrasco and Cerro, Montevideo, and at Arroyo Santa Lucia, Florida; copper-silver is found at Pan de Azúcar, in Maldonado; copper exists in Minas; iron ore in Pantanoso, Montevideo; Minas and Areicua, Rivera; and manganese in Rivera. To encourage and assist mining projects, all machinery, tools, and other articles necessary for investigating and operating mines and erecting metallurgical establishments are exempted from customs duties. There are good opportunities for investment in mining properties in Uruguay, the Government welcomes and protects such enterprise, and labor is cheap in the Departments where minerals abound.

Palladium is an article of commerce, though in extremely small quantities. The quantity of palladium imported in 1908 was but three one-hundredths of a pound. This small quantity was, however, valued at \$21, a pound therefore being worth approximately \$700. In other years the quantities imported have been much larger, amounting in 1905 to over \$10,000 in value, and in 1904 to more than \$16,000. This rare metal, associated with platinum, while found in its native state in small quantities in Germany and Brazil, is chiefly supplied from the working over of platiniferous residues of various mints, and is used in the manufacture of astronomical instruments, and by dentists, when alloyed with silver.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

J. J. M.: Cassiterite.

J. A. R., Las Vegas, Nevada: Galena, malachite, pyromorphite, and no reaction for tungsten.

D. L., Pioche, Nevada: No. 1, indurated clay; No. 2, clay-shale; No. 3 calcite (limestone); No. 4, calcareous shale, with crystals of calcite.

I. M. K., Nelson, Nevada: No. 1, arsenopyrite, pyrite, and pyrite altered to hematite; No. 2, pyrite and fine grains of magnetite in calcite and quartz; No. 3, serpentine; No. 4, dacite, stained with hematite.

I. J. S., Silver City, New Mexico: No. 1, altered syenite; No. 2, syenite and pyrite; No. 3, biotite syenite discolored by hematite; No. 4, syenite discolored by hematite; No. 5, altered syenite; now largely an aggregate of kaolin and talc.

C. C. G., Ocotlán, Oaxaca, Mexico: No. 1, dacite, badly altered; specimen too small for accurate determination; No. 2, syenite and pyrite; No. 3, pyrite in quartz stained with hematite; No. 4, chalcopyrite, pyrite, and galena in quartz; No. 5, olivine diabase; No. 6, specular hematite; No. 7, altered dacite; No. 8, a vesicular lava, probably rhyolite, containing magnetite and limonite; No. 9, quartz in contact with altered syenite; No. 10, pyrite in decomposed basic rock, now mostly talc; No. 11, pyrite in quartz stained with hematite; No. 12, nepheline syenite; No. 13, galena and chalcopyrite; No. 14, granite or granodiorite; No. 15, aggregate of quartz and decomposed feldspar; No. 16, iron-stained quartz; matrix inadequate for determination; No. 17, syenite.

The tantalum of the Black Hills occurs in the mineral columbite. The known deposits of columbite in the region have been described in detail by F. L. Hess. Tantalum is used in making filaments for incandescent electric lamps.

COMPANY REPORTS.

AMERICAN SMELTING & REFINING.

The annual report of the American Smelting & Refining Co. for the fiscal year ended April 30, 1909, shows net, after all charges and dividends, a total of \$1,843,050, as compared with a surplus of only \$11,191 in the previous year:

| | 1909. | 1908. | 1907. | 1906. |
|-----------------------|-------------|-------------|--------------|--------------|
| Gross | \$9,146,387 | \$9,403,282 | \$13,250,058 | \$11,665,885 |
| Betterments | 797,072 | 933,129 | 976,534 | 828,582 |
| Balance | 8,349,315 | 8,470,153 | 12,273,524 | 10,837,303 |

| ment charges. | 2,054,705 | 2,068,505 | 2,639,301 | 2,920,865 |
| Profit and loss | | | | |
| surplus | 15,251,268 | 13,408,218 | 13,397,028 | 10,482,775 |
| Total | 117,542,973 | 115,825,724 | 116,932,380 | 116,313,606 |

Notwithstanding the depression in business operations during the period covered by this report, after paying quarterly dividends, amounting to 7% on the preferred stock and 4% on the common stock, there has been carried to surplus account for the year \$1,843,050. This increase of surplus is largely shown in the cash and demand loans, amounting to \$1,730,204. All expenditures on the plants on account of repairs and betterments, as well as improvements and new construction, have been charged to profit and loss account, and expenditure has been made to improve efficiency of the plants and their ability to operate economically. Expenditures for new construction and improvements were \$300,861 less than the previous year. The company owns 177,510 shares of the common stock of the American Smelters' Securities Co., of the par value of \$17,751,000, carrying control.

At the time the Securities company was organized it was believed that the company would be obliged to advance, under its guarantee, some portions of the dividends accruing on the series B stock, until the Securities company was able fully to operate its projected smelting plants. No such advances, however, have been made. Under mortgage requirements the outstanding bonds of the Omaha & Grant Smelting Co., maturing in 1911, have been reduced by \$112,000, leaving but \$237,000 outstanding.

The report of the Securities company shows that the earnings for the first six months of the year amounted to but \$1,318,146, while for the last six months they reached \$2,308,280. The projected new construction has been nearly completed, and the mining properties are now being efficiently and economically operated. Expenditures for ordinary repairs, betterments, new construction, and improvements, charged to profit and loss, have amounted to \$1,276,726.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

POCKET-BOOK OF USEFUL FORMULAE AND MEMORANDA FOR CIVIL, MECHANICAL, AND ELECTRICAL ENGINEERS. By Sir Guilford L. Molesworth and Henry Bridges Molesworth. Small 12mo., pp. 899, Ill. E. & F. Spon, New York, 1908. Price \$2.

This is the 26th edition of a handy little volume which contains tables, formulae, and short-cut solutions of a large number of problems. It covers surveying, strength and weight of materials, earthwork, masonry, framed structures, hydraulics, mill-work, workshop methods and recipes, general machinery, steam engineering, power application, and quite extensively reviews the subjects of algebra, trigonometry, calculus, and conic sections, with special reference to their practical utilization.

TABLES OF THE PROPERTIES OF STEAM AND OTHER VAPORS, AND TEMPERATURE ENTROPY TABLE. By Cecil H. Peabody. 8vo., pp. 138. John Wiley & Sons, New York, 1908. Price \$1.

The tables in this work have been entirely re-computed, following the experimental investigations of Callendar, Barnes, Knoblauch, and Thomas. All the tables for saturated steam have columns of entropy due to vaporization, and the table in metric units has been made into a conversion table, by aid of which properties can be found in either metric or English units. The temperature-entropy table gives solutions of all adiabatic problems, both for saturated and for superheated steam. The tables are preceded by an elementary discussion of the properties of steam.

MINERAL RESOURCES OF THE KOTSINA-CHITINA REGION, ALASKA. By Fred H. Moffit and A. G. Maddren. U. S. Geol. Survey, Bull. 374, pp. 103, Ill., map. Washington, 1909.

This is a timely report containing much fresh data on the region from which mineral was first reported, 1741, in Alaska, and one which is now attracting considerable attention because of the development of deposits of the same mineral—copper.

Commercial Paragraphs.

H. R. WHITEHEAD, formerly with the United States Mint at Denver, is now associated with The Elspass Engineering & Mining Machinery Co., Denver, Colorado.

S. B. BELDEN has been promoted to the position of sales manager in the mining machinery department of The Jeffrey Mfg. Co., with headquarters at Columbus, Ohio.

The WESTINGHOUSE ELECTRIC & MFG. Co. has removed the sales office formerly situated at Tucson, Arizona, to 173 San Francisco street, El Paso, Texas, where it will be continued as a branch of the Los Angeles office.

The POWER & MINING MACHINERY Co., Cudahy, Wis., has lately secured an order for a converter plant from the International Smelting & Refining Co. The installation consists of 5 stands and 12 shells, 96 by 150 in., electrically operated.

Catalogues Received.

ATKINS, KROLL & Co., San Francisco, have issued a leaflet discussing the uses of ferro-alloys in foundries.

THE TRENTON IRON Co., Trenton, N. J., has just published a new catalogue giving complete description and many views and drawings of Bleichert aerial tramways.

THE DIAMOND FIRE BRICK Co., Canon City, Colorado, issues a neatly bound catalogue giving the shapes of silica and fire brick and fire-clay tile which it carries in stock.

THE JEANESVILLE IRON WORKS Co., Hazelton, Pa., is distributing its Bulletin No. 30, describing centrifugal pumps. The company reports that its business is greatly increasing, and that it has recently received orders for a number of large pumps.

MINING AND METALLURGICAL PATENTS.

ROASTING-FURNACE.—No. 919,000. John E. Greenawalt, Denver, Colorado.

In a reverberatory roasting-furnace, the combination of a porous hearth supporting the ore in its passage through the furnace, a rabble for working the ore through the furnace and over the porous hearth, and means for delivering air or gases to the porous hearth whereby it is caused to pass through the pores or interstices of the hearth to the ore mass.

APPARATUS FOR USE IN SOLUTION AND PRECIPITATION PROCESSES.—No. 918,749. Woldemar Hommel, London, England.

In an apparatus for use in solution and precipitation processes the combination of a rotatable horizontal cylindrical barrel a door for the introduction of solids at one end of the barrel and a central inlet pipe for the introduction of fluids, a tapering outlet at the other end of the barrel, an outlet valve at the end of the tapering outlet, and spiral channels arranged in the drum and in the tapering outlet for the purpose of mixing the solids and fluids and conveying the flowing mixture through the apparatus.

ELECTRIC AIR-COMPRESSOR.—No. 918,194. Augustine J. Pockock and Richard E. Allgire, Dayton, Ohio.

In an air-compressor, the arrangement of the circuits of air and cooling medium by arranging a plurality of cooling devices with a plurality of compression devices and a pump and conduits directing the cooling medium from the pump direct to each cooling device, means for discharging the cooling medium from each cooler to the compressor jacket, and means for directing the air from each compressor cylinder to a cooler in a direction opposite to that of the cooling medium circuit, substantially as specified.

TRANSPORTING APPARATUS FOR MINES.—No. 918,661. Alfred E. Davis, Johannesburg, Transvaal.

In apparatus of the nature specified, in combination, a

vehicle body, dish shaped bearing pieces secured to the bottom of the body and forming recesses on the underside, an eyebolt revolvably carried by each bearing piece, a pivot plate revolvably mounted on each eyebolt, a bogie carriage for each bearing piece constructed in its upper portion with holes and a pivot pin for each carriage engaging the holes in the upper portion thereof and engaging holes in the pivot plate and eyebolt.

ELECTRIC FURNACE.—No. 917,796. James H. Reid, Newark, New Jersey.

An electric furnace having a plurality of horizontally extending electrodes of different polarity adapted to constitute a table within the furnace and to produce arcs between, and a sweep adapted to spread the ore on the electrodes and clean it off the same.

ROCK-DRILL.—No. 917,074. Corwill Jackson, Madison, Wisconsin.

In combination, a rotating body having a chamber formed in it, a hammer member located in said chamber and free to move axially therein under the action of centrifugal force, the centre of gravity of said hammer member being at one side of a line radial to the axis of rotation and perpendicular to the line of movement of the hammer, a device in a position to be struck by said hammer, and means for cushioning the hammer when it rebounds after each blow.

HAMMER-DRILL.—No. 919,270. Daniel S. Waugh, Denver, Colorado.

In an instrument of the character set forth, the combination with a cylinder member, of a piston operating in the cylinder member, a valve casing having a valve chamber, an inlet and exhaust conduit for the cylinder member communicating with one end of the valve chamber, and a valve operating in the chamber and having an internal exhaust passage provided with an inlet that opens through the end of the valve and communicates with the end of the chamber with which the conduit communicates.

EDITORIAL.

NANKING is to have an exposition in "the fifth moon," otherwise May, next year. Thus civilization creeps up the Yangtze.

PASSENGER trains have begun to run north from Valdez. The journey as yet possible is only 43 miles, but at fifteen cents per mile that is perhaps enough.

ATLANTA is the last camp developed in Nevada. Discovered by a plucky woman prospector, all gallant miners will hope it may not disappear under closer investigation, as did the fabled Atlantis.

ZINC in ores containing over 20 per cent is hereafter to pay a tariff of one cent per pound, but in ores containing less, a lower rate. Considering the fact that zinc ores containing less than 40 per cent can not be economically imported, this saving clause is not likely to be of much comfort to the zinc smelters.

IRRIGATION will be discussed in all its phases at Spokane next week, and the following week the Trans-Mississippi Commercial Congress will assemble at Denver. The vexed question of railway rates and the relations of the Forest Service to the Department of the Interior are likely to provoke lively tilts at both meetings.

LAND which is unappropriated and unreserved is still more common in the United States than many realize. In 1908 there were 754,895,000 acres, of which, however, approximately half was in Alaska. The principal waste land in the East is that which is swampy and subject to overflow. Of this there are over eighteen million acres in Florida alone.

WAGON ROADS will no longer be admitted as available toward meeting the requirements for expenditures on mining claims prerequisite to patent. By a decision of the Secretary of the Interior on January 21 of this year, such work, whether performed on the claim itself or on adjoining claims, is rejected. The Regulations, however, make an exception where it can be clearly proved that the construction of the road is essential to the exploitation of the deposit.

KENTLAGE, on which the new tariff is to be \$2.50 in place of \$4 per ton, is not so mysterious as it sounds, being merely pig iron laid in the hold for ballast. The origin of the term is not altogether certain. Apparently 'kent' goes back to the Danish 'kant', an edge or border, hence a corner, an angle, a slope, or a sloping position, as when a boat is 'canted', which naturally results when it is propelled

or pushed along. 'Ledge', from having served for shelf, has come to mean to naval architects a piece of the deck frame lying between the deck beams, and in this way the combined words serve to indicate that which is laid down in a boat. By such curious paths do words come to serve us.

ENTRY of the railroad from Mexico into Guatemala is a notable event. It opens the country to American capital as never before. Central America is almost a virgin country in the development of its mineral resources, and Guatemala has remained in the rear of its neighbors in this respect. But the Republic is reputed to possess important deposits of lead and zinc, and in certain portions gold is found in the streams. Iron and manganese are also reported. We publish in this issue extracts from the Mining Law now in force, which is liberal both to native and alien. It would seem, however, that the law is lacking in coherency, and might easily lead to troublesome litigation. Under such circumstances, foreigners organizing mining companies in Guatemala would naturally seek special charters as a means of protection.

POLITICS in Costa Rica turn on the question of monopolistic control, so familiar at home, and also the material out of which party slogans are made in Mexico. The issue in Costa Rica, with Señores Jimenez and Iglesias as rivals, standing respectively for and against the dominance of the United Fruit Company, involves also the delivery of the minerals of the country into the hands of monopolies. The Abangarez Goldfields of Costa Rica, a child of the United Fruit Company, holds a princely concession in the northwestern corner of the Republic, where it is operating gold-mills. This concession is practically in perpetuity. Other concessions, tying up still larger areas, are contemplated. The system in principle is bad. The only mitigation would be to farm out the minerals on these territories to corporations, reserving certain public rights in their exploitation. But that is not the way of the Spanish Americans. Concessions as there extended give rise to the policy which we know as that of the dog in the manger.

The Selby Fume Case.

It has been our privilege on several occasions to call attention to the spirit of fairness shown by the Selby Smelting & Lead Company in its efforts to settle the questions arising from annoyance caused by smelter fume. This week we print an article by Mr. Eugene B. Braden, vice-president of the Selby company, which is an instructive exposition of the trials of a modern smelting company. The struggle is with a prejudice against which argument is unavailing. The case now before the court is all the more interesting because it is not confused with blackmailing motives. No damages in money are sought; a community considers itself injured; it seeks relief; and such relief, according to its view, would involve the closure of the smelter. It is not uncommon for a certain class of speculators to take up agricultural lands in the vicinity of new smelters

for the purpose of being 'damaged' by fume, thereby hoping to reap a double harvest. It used to be the custom to placate farmers in the vicinity of smelters by paying bounties; but the spirit of graft grew so insistent that the smelters have been forced to adopt sterner policies. The case of the Selby smelter, however, is today detached from considerations of monetary damages. The residents of Benicia are so sure that only a smelter can produce bad odors that they refuse to believe it when the smelter is shown to be closed and every furnace cold. The continuance of the suit for permanent injunction is surprising, after it was demonstrated to a committee of reputable citizens from the town of Benicia that the odors complained of were in evidence even when the fires were all drawn at the works. It shows how blinding a force is prejudice.

The Selby company has been making notable experiments to overcome the nuisance from smelter fume. Among these is the application of the principle of the electric discharge through the smoke, causing precipitation of all solid matter, including sulphuric anhydride. This device, elaborated by Mr. F. G. Cottrell, professor of physical chemistry in the University of California, has reached a state of perfection such that the fume passing through the chambers issues free from all substances except fixed gases. As a result of the bag-house and the Cottrell apparatus combined, no injurious or noxious gases are today issuing from the Selby smelter. This is to be proved in court, and the case appears to be so clear that a denial of the petition for injunction seems assured. A favorable verdict will have a wide-reaching influence, as did that of Judge Hunt at Anaconda, but in a different way. The Anaconda case involved construction of a point at law; that some damage had been done was not denied; it was a question whether injury to a few individuals might be made the cause for suspending a great industry and thus pecuniarily injuring a large number. The Selby case involves no balancing of conflicting interests; the ascertainment of the fact of injury, or not, from smelter fume is the concern of the Court. That the nuisance has been caused by fume from oil-refining seems practically certain. Tests of the air affected by the refinery fume show the presence of hydrogen sulphide and allyl sulphide, the latter possessing a pungent odor, resembling garlic, which is not esteemed in Benicia, since the population is not essentially Sicilian. Allyl sulphide is one of the higher organic compounds, in which sulphur replaces some of the oxygen atoms. Its odor is so penetrating that it may be detected even when the atmosphere contains only one part of the gas in sixty millions. It has also been shown that, of the gases issuing from certain oil-refineries on the Bay, about 20 per cent consists of allyl sulphide, and other ethylene hydrocarbons offensive to the smell. The vindication of the Selby plant will be a great victory for the smelting industry in general; it will demonstrate, not that such works must be tolerated for the greater benefit they confer, but that they are no longer a detriment to the health of the community in their neighborhood. How any other decision can issue, in the face of the facts known to us, is inconceivable.

Producing Cost of Copper.

A striking analysis of the copper production of America was made by our contemporary, the *Boston News Bureau*, that merits consideration by those contemplating the development of new properties. The argument is similar to that which we had already stated, which is based on more elaborate figures, namely, that low-grade ores are dominant. It is from the low-grade deposits that the cheapest copper is being produced. The world has learned that flashing superficial displays of high-grade copper ore are deceptive; that the great copper-mining industries of the world are not founded upon any such basis. The lowest-cost copper district in America today is Michigan, where the total expense falls below 8 cents per pound, and it is at the same time the district in which the average copper-tenor of all ores mined has been lowest, namely, $2\frac{1}{2}$ per cent. The Ely district, in Nevada, is approximately the same as to percentage of metal and cost of production. This parallelism is merely accidental, for the conditions of mining and treatment are utterly dissimilar in the two regions. The interesting thing is that, given a large mass of low-grade ore, whether it necessitate deep mining or may be scraped off from the surface with a steam-shovel, the mere largeness of volume admits of inexpensive operation, which yields better returns than can be won from the higher concentrations in veins of moderate size.

The total copper output of the United States now amounts to about 1,300,000,000 pounds per annum, of which 35 per cent is produced at less than 9 cents per pound, and 38 between 10 and 11 cents, while 13 per cent is marketed at a cost higher than $12\frac{1}{2}$ cents, which for the most part represents a loss to the producer. It is estimated that the average cost of the entire copper output of the United States is 10 cents per pound, which does not take account of all capital and construction expenses. When all items are included, the average cost will approximate $10\frac{1}{2}$ cents per pound. The method pursued by the Calumet & Hecla is worthy of emulation by other corporations; all outlay, whatever be its character or amount, is instantly charged in the department to which it pertains, and affects the final estimate of the cost of production. No effort is made to juggle with the item by spreading it over a period of years to which it might be assumed as applying. Then and there it goes against the cost of the metal. It may hurt immediate profits, but in the end the law of averages will adjust the accounts. An enterprise is successful only when its total income is exceeding total outgo.

On the showing made it is evident that the limit of cost for permanently prosperous copper mines is approximately 11 cents. The bulk of the output, or 525,000,000 pounds, is from mines where the costs approximate that figure. In this class are found the Anaconda, Osceola, Quincy, Mohawk, Boston Consolidated, Greene Cananea, Granby, Old Dominion, and Detroit. These are all great properties, but several of them experienced serious embarrassment during the recent financial crisis. Evidently safety requires that new promotions should be based on estimates not in excess of 10 cents per pound.

BY THE WAY.

Inks, Ancient and Modern.

Mr. George H. King, recently discussing the chemistry of ink before the Colorado Section of the American Chemical Society, said:

Ink in some form became a necessity with the step beyond inscription on clay or stone. Dye stuffs were commonly used by the ancients. The earliest inks were in the form of pigments held in suspension by some gummy substance, either vegetable or animal. They were used with a brush or a reed pen. Blue and black have been favorite colors from the beginning, while red was used in the early books and papers for illuminating capital letters and headings. Lampblack, very commonly used, was made by the burning of oil, tar, or rosin, and mixed with gum or honey and kept in cakes or wafers until wanted for use, when water was added. This, of course, made only a sticky, colored mixture, but with the use of reed pens the requirements were not so great as those demanded at the present day for use in our fountain pens. Indigo was used in India and Egypt long before the Christian era. The quill pen came into use about the sixth century. This allowed a greater degree of latitude in writing, and the inks were made thinner than those used with brush and reed pens, and were necessarily of a less durable character, departing oftentimes from the lampblack and indigo, which were always good. Two centuries later the black ink formulas showed a marked improvement. India or Chinese ink was really the first practical ink, so far as durability or lasting qualities are concerned. This, having a finely divided carbon as its base, was to be relied upon, but, being made into cakes and used with a brush, as used by the Chinese at the present day, it was not suitable for use with any kind of a pen. In the twelfth century nut-gall ink was first brought into use. The term 'gall-ink' refers to that made from nut-galls or tannin with iron sulphate and some gummy vehicle. For several centuries this was the standard used, and many are the documentary monuments standing to its credit. The writer has in his possession a number of fine specimens, some of which are several hundred years of age, written in the original Latin and Spanish, the characters of which still retain their pristine blackness.

The inks of today may be classified as black writing ink, chemical writing fluid, colored writing fluid, copying ink, safety ink, India or Chinese ink, and the secret or sympathetic inks. The latter, however, is little considered, as it has no standing or commercial value. Copying inks are usually made by the addition of sugar, glycerine, or glucose to the ordinary writing fluid. The requisites of a good black writing ink or black writing fluid are that it flow readily from the pen, indicate in a short time a black color, and penetrate the paper to an appreciable degree, and, more important than all the rest, be of great durability. When kept in a closed vessel no sediment of any account should be precipitated. Previous to the discovery of the soluble anilines, which became practical about 1874, logwood, madder, orchil, and other dye-stuffs were used.

PATENTS AND THE PATENT OFFICE.

At a recent meeting of the New York section of the American Chemical Society W. H. Swenarton contributed the following to the discussion:

The trade mark is a development of the ancient shop sign. Even the Egyptians are known to have displayed inscriptions denoting their trade in conjunction with an emblem to further indicate it. Also among the ancient Greeks signs were employed to proclaim their calling. In the ruins of Pompeii and Herculaneum discoveries are reported of representations of various kinds, let into the pilasters at the side of an open shop, as, for example, a goat by a dairy; a mule driving a mill at the baker's, and at the door of the school-master's, what has been termed, "the not over-tempting allurements to knowledge," comprising the representation of a boy receiving a good birching. These trade emblems were doubtless introduced into England at the time of the Roman invasion.

Originally, owing to the limited number of traders, the signs were indicative of the trade, and were employed in the same capacity as we now use street numbers. Gradually, as competition increased in these particular trades, and the shops became designated by street numbers, the sign-board fell into disuse. Then it was that the trade mark came into active use, being merely in the beginning a transfer, so to speak, from the door of the shop to the article of merchandise. A critical review of famous trade marks would form an interesting lesson in psychology, and would doubtless supply a fund of useful information to the memory-system doctrinaires.

No consideration of the influence of invention upon industry can be complete without a review of the functions of trade secrets. The influence of trade secrets upon industry has been marked, from the earliest times. The guilds of the Middle Ages are famed for theirs. It is often, however, feasible to take out patents, and there are those who still believe with the examiner who was appointed to the Patent Office in 1854, and who upon resigning shortly after declared: "I believe in a little while there will be nothing for the Patent Office to do, as everything is already patented, and I am going to get out of this and engage in some permanent business." It appears to be the same old story "that familiarity breeds contempt." On the other hand, the following from Karekiyo Takahashi, the special commissioner appointed by the Japanese Government to gather data regarding our Patent system, may be quoted:

"You will remember that it is only since Commodore Perry in 1854 opened the ports of Japan to foreign commerce that the Japanese have been trying to become a great nation like the other nations of the earth, and we have looked about us to see what nations are the greatest, so that we could be like them; and we said, 'There is the United States, not much more than one hundred years old, and America was not yet discovered 400 years ago'; and we said, 'What is it that makes the United States such a great nation?' And we investigated and found that it was patents, and we will have patents."

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

BERTRAM HUNT is in London.

W. H. SHOCKLEY is in London.

ROBERT H. RICHARDS is at Salt Lake City.

W. F. FERRIER has been in San Francisco.

R. GILMAN BROWN was recently in Cornwall.

E. C. THURSTON is temporarily at Geneva, Ohio.

C. S. HERZIG has reached London, from Nicaragua.

H. R. NORSWORTHY was in San Francisco this week.

HENRY LOUIS is studying the ore deposits of Algiers.

HERBERT HAAS was in London, on his way to Magellan, Chile.

DONALD F. FOSTER is with the Bibiani company, in West Africa.

S. J. TRUSCOTT has an office at 43 Threadneedle St., London.

J. PARKE CHANNING and H. C. HOOVER are motoring in Cornwall.

J. HARLAN HARTLEY, of San José, Costa Rica, was in San Francisco.

R. A. F. PENROSE, Jr., was in San Francisco and Los Angeles this week.

LIONEL LINDSAY is with the Bunker Hill & Sullivan at Kellogg, Idaho.

ROBERT T. HILL has returned from London and is now in southern Nevada.

A. F. McEWEN is superintendent for the Nova Scotia Co., at Cobalt, Ontario.

R. C. ALABASTER is now manager of the Oonah mine, at Zeehan, Tasmania.

W. H. HOBBS has been in the Yakutat Bay region of Alaska this summer.

ROWLAND FEILDING has left London to examine mines on the Irtysh river, Siberia.

GEORGE N. ROBERTS, manager of the Associated mines, at Kalgoorlie, is in London.

ROSS B. HOFFMANN sailed from Liverpool on July 24, returning to San Francisco.

GEORGE J. BANCROFT was in San Francisco, on his way to Yuma, Arizona, this week.

A. E. DRUCKER has been visiting the Bendigo and Ballarat districts of Victoria, Australia.

HENRY C. JENKINS has been appointed principal of the Redruth School of Mines, Cornwall.

W. J. ADAMS is now consulting engineer of the Jumper mine, in Tuolumne county, California.

R. A. VARDEN, of the firm of Bainbridge, Seymour & Co., is on his way to Baranquilla, Colombia.

EDWIN J. COLLINS, of Duluth, Minn., is examining gold and copper properties in northern Sonora.

F. L. BOSQUI has accepted a position with Wernher, Belt & Co., and will leave for London August 20.

LYDD D. SKINNER, of the Four Metals Mining & Smelting Co., Keeler, Cal., has been in San Francisco.

W. A. CARLYLE, the new professor of metallurgy in the Royal School of Mines, London, is in Norway.

T. A. RICKARD has resigned as a member of the council of the Institution of Mining & Metallurgy, London.

C. G. PATTERSON, engineer for the Butters Filter Co., is at Johannesburg; he passed through London in July.

S. J. SPEAK, of the firm of Hooper & Speak, has returned to London from a professional visit to the West Coast of Africa.

CHAS. J. BANDMANN has returned from a trip to Sonora, Mexico, and will leave shortly for Quatrino Sound, Vancouver Island.

FREDERICK GRUNDY returned last week to Los Angeles from examining properties in the Calico district, but left at once for Needles, California.

THEODORE J. HOOVER is in Asia Minor, where he is installing a metallurgical plant for the Minerals Separation Co. at the mines of the Caucasus Copper Co., Ltd.

COREY C. BRAYTON, for the last five years manager of Guggenheim properties in Missouri, California, and Mexico, has resigned and opened an office in the Clunie building, San Francisco.

Obituary.

The world lost one of its foremost scientific men in the death of Prof. Simon Newcomb, at Washington, D. C., Sunday, July 11. He was buried with the honors due his rank as a retired rear-admiral of the navy, the services being attended by President Taft and many men notable in the scientific world. Professor Newcomb was appointed professor of mathematics in the United States Navy in 1861; assigned to duty a short time later at the United States Naval Observatory; negotiated contract for and supervised construction of the 26-in. equatorial telescope; secretary United States Transit of Venus Commission, 1871-74; observed transit of Venus at Cape of Good Hope, 1882; became senior professor of mathematics in United States Navy, with rank of captain, and Director Nautical Almanac office, 1877-97; retired at age of 62, in 1897. Few men in this country have had such a profusion of honors heaped upon them as Professor Newcomb. He was foreign associate of the Institute of France—one of eight, and the only American to hold that honor since Franklin—and was medalist of the Royal Astronomical Society, of the Royal Society, of the Dutch Society of Sciences, and the Astronomical Society of the Pacific; he was given the Sylvester prize of Johns Hopkins and the Schubert prize of Russia; France in 1893 made him an officer in the Legion of Honor, and in 1907 promoted him to the grade of commander; Prussia bestowed upon him the unusual honor of knighthood in the Order of Science and Art. The most important work which he accomplished is an almost complete reconstruction of the theories of the motions of the bodies of the solar system. This great work involved at its foundation the complete revision of the so-called constants of astronomy. The distance of the earth from the sun; the displacement of the earth in its orbit by the attraction of the moon; the displacement of the stars due to the motion of the earth, combined with the motion of light, which involves the velocity of light and space; the yearly precession of the equinoxes; the obliquity of the ecliptic; the dimensions and the masses of the planets—all had to be worked into a homogeneous system to be used as a basis for the tables of the sun and planets.

ROBERT E. C. STEARNS died in Los Angeles, July 28, at the advanced age of 82 years. Mr. Stearns was prominently identified with public and scientific life of the Pacific Coast and throughout the United States. He was paymaster of the Lake Superior copper mines in the early 50's; deputy clerk of the California Supreme Court '62-3; natural history collector in Florida; assistant curator, department of Mollusks, Smithsonian Institution; and paleontologist on the U. S. Geological Survey. He was an honorary life member of the California Academy of Science.

S. P. JELLUM, of Elk City, died at Newsome, Idaho, July 12. He was a graduate of the University of Minnesota, a keen observer, and an excellent writer. He did much to stimulate the development of his adopted State, publishing an excellent little handbook entitled 'Some Central Idaho Gold Districts'.

Dividends.

On Wednesday, August 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid Dividend No. 143, of \$45,000. This makes the amount of dividends paid since January 1, \$435,000, and the total to date, \$11,106,000.

General Mining News.

ARIZONA.

COCHISE COUNTY.

At the Inspiration mine in the Miami district the Joe Bush shaft is being sunk 20 ft. per week. This is down 350 ft. and has cut a body of concentrating ore in the gray schist that averages 3% copper.—Shipments from the Black Warrior averaged 80 tons per day for July, which is an increase of 40% over the previous month. The ore is being stoped at the 300-ft. level.—At the Miami the main work is on the smelter and sinking the main four-compartment shaft. This will be put down 600 ft., as the orebody has been proved to that depth. The ore is a secondary chalcocite in an altered gray schist averaging 2% copper that can be concentrated in the ratio of 16 to 1.—The adit of the Princeton Mining & Smelting Co., in the Huachua mountains, is in 1700 ft. and a new compressor installed at the mine. Henry Hamburg, the manager, has purchased the adjoining claims from Abe Campbell.—Operations are to be resumed on the Willie Rose copper mine at Portal. A shaft is down 60 ft. in a fair-grade copper ore.

GILA COUNTY.

The Gibson Copper Mining Co. is shipping 10 tons of high-grade copper ore per day. The shipping ore averages 18% copper and the low-grade which is stored on the dump runs 3%. Most of the development work is on the fifth and sixth levels.—The development at the Hamilton shaft of the Cactus Development Co. is confined to cross-cutting from the 600-ft. level. T. W. Hamilton is superintendent.

GRAHAM COUNTY.

The Stevens Copper Co. is doing a small amount of development on its property at Metcalf. Operations are to be resumed shortly at the Chase Creek Copper Co.'s property. I. N. Stevens will be in charge of the work.—The Standard Consolidated Copper Co. is shipping regularly to the Morenci and Douglas smelters.—The Coppermines Co. of Arizona has purchased two 8-in. churn-drills to prospect its property in the Clifton-Morenci district. J. O. Baylor is superintendent.—The Fumarole mine, 12 miles from Saford, has been closed down until a new power plant can be installed. F. A. Woodward is manager.

MARICOPA COUNTY.

E. C. Rogers & Son have sold their property in the Bill Williams district for \$32,000 to Lyman & Co., of Los Angeles, who are representing Eastern capitalists.

MOHAVE COUNTY.

The vein in the face of the drift on the 70-ft. level of the Ruth mine is in \$60 ore.—The shaft of the Carter Gold Mines Co. is down 100 ft. A machine-drill has been installed and better progress is expected.—Rich ore is being sacked at the Bonanza mine for shipment to the El Paso smelter. Ed. Patterson is the owner.

YAVAPAI COUNTY.

The Penn-Arizona Mining Co. has completed the unwatering of the Mudhole mine at Walker and is installing the new electric hoist. The new shaft is down 230 ft. and has opened a body of sulphide ore.—The first unit of the lead smelting plant to be erected at Mayer will have a capacity of 100 tons per day. The management will rely chiefly on the Bodie mine for its supply, but there are a number of mines in the district that could work their ores if it were not for excessive freight rates. In the Turkey Creek district the Silver Chord mine has a large tonnage of lead-silver ore blocked out. In the Tip Top district the Brooks mine is credited with a similar output. The Black Warrior, Silver Prince, Peck, Crown King, and a number of smaller properties in the Bradshaw mountains will be tributary to this plant.—The La Garcia Gold & Copper Mining Co. has taken over the Red Bluff group, six miles east of Dewey. All litigation in which the old company has been engaged for two years has been settled, and the new company will install a new surface plant and resume operations. A 4-ft. vein of copper-gold ore has been opened

on the property in the Yavapai schist belt.—At the New Cumberland mine at Pine Flat the development work is confined to driving and blocking out ore on the 300-ft. level. The mill will be started as soon as a supply of water is available.—The Blue Bell mine has been unwatered and cross-cutting started on the lower level.—At the Silver Mountain group, eight miles south of the Crown King mine, a series of veins have been opened by a 300-ft. shaft and an 800-ft. adit. F. X. O'Brien is manager.—The Eleanor Placer Mining Co. has purchased the machinery for a dredge and is hauling lumber for the boat to French gulch. The company owns 1440 acres one mile east of Walnut Grove. The dredge will be of the suction type and have a daily capacity of 1500 cu. yd.—The dredge of the Speck Mining Co. on Lynx creek has been started with satisfactory results. The company owns 160 acres on which the gravel is from 8 to 12 ft. deep.

CALIFORNIA.

ELDORADO COUNTY.

The McGeachin Mining Co. has purchased the Morning Star mine from Harold T. Power and D. W. Lubeck for \$20,000. The company owns the McGeachin, Jupiter, and Big Dipper properties.—The Mt. Pleasant Mining Co. is re-opening its mine near Grizzly Flats. The 10-stamp mill has been repaired and cross-cuts started from the 600-ft. level. F. C. Van Schaick is manager.

INYO COUNTY.

On the Golden Siren group, 17 miles from Bishop, a shaft has been sunk 50 ft. on a vein which assays from \$40 to \$100 and varies from 1 to 3 ft. in width.—Sim & Reeder have sunk a 26-ft. shaft on a 14-in. vein of good milling ore.—On the property of John Beauregard an inclined shaft is being sunk in a 3-ft. vein, 6 in. of which is of shipping grade.

MARIPOSA COUNTY.

A 2-stamp mill is being erected on the property of the Trujillo Mining Co. at Grizzly Flats. A 100-ft. shaft has been sunk on the vein that assays \$25 per ton. C. G. Lewis is superintendent.

NEVADA COUNTY.

(Special Correspondence).—By August 9 the Brunswick company expects to commence sinking a vertical three-compartment shaft to a depth of 1200 ft. C. A. Mallen is superintendent.—The old Cornish pump has been extracted from the Empire shaft and the two new electric centrifugal pumps are being installed.—The adit at the Fruitvale is in 400 ft.—The Greek vein at the Union Hill is showing up well. Clifford A. Graham is superintendent.—The 8-ft. vein on the 500-ft. level of the Idaho-Maryland continues to assay well. Twenty stamps are dropping in the mill.—A 20-in. streak of rich ore has been opened in the 4-ft. vein on the 400-ft. level of the Yuba mine. Samples run \$100 per ton. T. M. Chase is superintendent.—William Graham and associates are installing an elevator at the Brophy ranch to treat a large deposit of gravel.

Grass Valley, August 3.

Considerable high-grade ore is being opened on the 400-ft. level of the Yuba mine near Washington. T. M. Chase is superintendent.—A 200-ft. shaft is to be sunk at the Mountaineer mine near Nevada City. The Mountaineer property is nearly three miles long and is one of the most consistent producers of that district. The shaft will be inclined to cut the vein system of the country.—There are 14 men working at the A. J. Quigley gravel mine near Grass Valley.

PLACER COUNTY.

A raise is being driven from the 2400-ft. adit at the Golden West gravel mine to tap the channel. E. H. Armstrong, of Grass Valley, is the principal owner.—The shaft of the Lukens mine is down 80 ft. and has cut a good vein of milling ore.—Good ore is being taken out of the Alameda and Annie Laurie claims.

SAN BERNARDINO COUNTY.

The streak of high-grade ore recently cut by the raise in the Big Chief property has widened to 6 in. and the richer portions assay from \$8 to \$10 per pound. This is the richest ore found in the district and is being sacked for shipment.

—J. S. Reece and associates have opened a body of silver ore on their Pearl property in the Silver Lake district. The prospect was located for its copper content, but the ore has changed completely in character from the outcrop, and now assays 400 oz. silver per ton. Considerable nickel and cobalt is present.

SHASTA COUNTY.

The excavation for the new ore-bins at the Mammoth smelter has been completed and the foundations are being installed. The bins will be 160 ft. long by 30 wide and will be the terminal of the recently completed tramway.—The Balaklala Consolidated Copper Co. is experimenting with a bag-house to remove the harmful gases from the smelter smoke.—The Gold Leaf narrow-gauge will be in operation in a short time, and the properties in the Lower Springs district west of Redding will have an opportunity to ship their silicious ores to the Mammoth and Balaklala smelters for flux.—The Onn Copper Mining Co. has been organized to operate the Spread Eagle group northwest of Copley.—A 20-hp. gasoline engine has been installed at the South Fork mine near Igo to run the compressor. Harold Rogers is in charge of the work.—A 90-ft. winze has been sunk on the Franklin property from the face of a 270-ft. adit, and a drift driven 126 ft. on a 4-ft. vein that assays \$60 per ton. On a 7-ton shipment of concentrate to the Selby smelter the net return was \$350 per ton. H. F. Musser is superintendent of the property, which is situated at French Gulch and owned by the Western Exploitation Co.—Al. Prater has leased the Texas mine in the Old Diggings district and is shipping the ore to the Balaklala smelter for flux. The property has been idle for several years.—Lessees on the Mammoth quartz mine in the same district are shipping flux to the smelters.

SIERRA COUNTY.

A 25-ft. drift from the cross-cut adit opened an ore-shoot in the Twenty-One mine near Alleghany that contains considerable free gold.—Development work is to be started on C. C. Ward's Oriflamme mine.—The 10-stamp mill at the Rainbow has been started, the initial run being satisfactory.—The Four Hills mine above Downieville is being re-opened. The Four Hills has an excellent record for past production, and with modern methods should become an active producer.—The San Juan ditch is being repaired to carry water from the Middle Yuba river to the Delhi mine.—A car, rails, and blacksmith outfit has been packed to the Golden Scepter mine and an adit will be driven through the bedrock to tap the old channel.—The drift at the Rosasco mine is in a fair grade of milling ore and it is expected to open the rich shoot at any time.—The Claybank mine near La Porte is being re-opened. The adit has been cleaned out and drifts will be started in the gravel. Several attempts have been made to open the channel previously, but have proved unsuccessful, as the ground is very heavy.—C. W. Root is opening a drift-mine on the old channel near Gibsonville.

TRINITY COUNTY.

The Fairview mine at Papoose has shut down and is to be abandoned. All the improvements are being sold off. The company is reported to have lost \$350,000 in fruitless prospecting. The Fairview five years ago was the most important quartz mine in Trinity county, employing 150 men and supplying ore to keep a 40-stamp mill in operation.—Wilson & Ehrmann have leased the Knob mine in Eastman gulch from Joseph Gifford. The ore assays from \$350 to \$400 per ton.—Paulsen Bros. & Richards are shipping \$200 ore to the Selby smelter.—The mill of the Brown Bear at Deadwood is running continuously on high-grade ore.—The Lappin company is installing an electric-power plant. The current will be furnished by the Northern California Power Co.—The West Point Mining Co. has a lease on the Leas & Nichols mine and is building ore-bins and a tramway to convey the ore to the Black Bear mill.—A new car and a lot of rail has been shipped to the Oversight mine in the Yellow Jacket district.—On the Pioneer claim of the Blue Jacket group a 3-ft. vein has been cut that assays \$15 gold and 4 oz. silver per ton.—J. L. Kendrick & Co., of Boston, is to resume operations at the Detroit and

Brooklyn mines.—The Trinity River Mining Co. will complete its tunnel through the neck of the horseshoe bend on the Trinity river about the 15th of the month. A power-plant that will generate 1800 hp. has been installed at the mouth of the tunnel to furnish power to work the river bed.

TUOLUMNE COUNTY.

The Californian General Mining Co., a syndicate of London and Paris capitalists, has purchased the Jumper mine at Stent from the Jumper Gold Syndicate and has commenced re-opening the property. W. J. Adams is consulting engineer.—Some excellent ore is being mined by tributers at the Santa Isabel mine near Quartz. It is understood that the company may work the mine in the near future.—The Josephine mine near Algerine has been bonded by local men who will incorporate to work the property.

COLORADO.

BOULDER COUNTY.

The San Juan Exploration Co. is testing a tract of ground at Goldhill to ascertain its value as a dredging property. O. J. Potter is in charge of the work.

CLEAR CREEK COUNTY.

(Special Correspondence).—A company of Eastern men has secured the Eclipse adit holdings on Saxon mountain, and work was put under way the first of the week. The Eclipse adit, now in 1000 ft., will intersect the entire vein system of Saxon mountain, the portal being 800 ft. to the west of the Doric. S. D. Farout is in charge of the work.—G. J. Hite has started a new adit on the Sonora property on Griffith mountain, and by driving about 250 ft. the heading will cut under the point whence a production of \$40,000 was made a few years ago.—Surveyors have been at work for several days in going over the ground near the Doric adit where the new mill of the Griffith Mining Co. is to be erected. W. D. Hoover, of Denver, is manager.—A carload of concentrate was shipped last week from the Stevens mine. C. L. Tingle is in charge.—Heavy shipments are being sent out from the Wilcox adit. A force of from 30 to 40 men is being employed on company account. Stopping is under way and a body of ore is exposed on the Paymaster vein that is from 8 to 30 in. wide.—A rich find has been made in the King Bee mine that is being operated through the Newhouse tunnel. The discovery was made at a depth of 2200 ft. and at a distance of 12,000 ft. from the portal of the tunnel. The initial mill run was settled for on the basis of \$335 per ton.—Moonan & Oxley shipped a carload of smelting ore last week from the Lamartine mine that milled 2.18 oz. in gold and 18 oz. in silver, with 15% in lead. These lessees are stopping on a body of mineral that is from 10 to 18 in. wide.—The Josephine mine on Donaldson mountain has been secured under bond and lease by H. M. Corwin and associates, of Denver. The mine is equipped with a modern concentrating plant and was a heavy producer previous to four years ago.—O. W. Lowell, of Idaho Springs, has secured a lease upon the Sun and Moon mine and arrangements have been made to work it through the Newhouse tunnel.

Georgetown, August 1.

LAKE COUNTY.

The Carbutt, King Solomon, Niger Infant, Saint Crispen, and Maud Hicks claims on Breece hill have been consolidated and will be worked through the Carbutt shaft, which is now down 400 ft.—A new shaft has been started near the old Seneca incline to open the Seneca and Martha claims.—The drift on the Boulder property of the Little Evelyn Mining Co. on Little Ellen hill is being driven on a streak of high-grade ore. The shaft is to be sunk 460 ft. and lateral work started from that point. J. B. Stewart is manager.

OURAY COUNTY.

George Craft has leased the old Silver Bell mine east of Ironton.—A rich vein has been cut in the San Antonio mine in the Red Mountain district. A cross-cut from the main drift opened a 16-ft. blind lead that assayed 20% copper, 12 oz. silver, and \$1 gold per ton.—The Comotion Gold Mining Co. has opened a good body of ore and will commence shipping at an early date.—A gasoline engine and

compressor have been installed at the Amity Gold Mining Co.'s adit. Some excellent ore has been opened in the mine. F. J. Campbell is in charge of the work.—The old compressor has been taken from the Atlas mine to the San Pedro and a new 8-drill machine is to be installed at the Atlas.—John Donald has leased the Jonathan mine and has opened some rich ore.—The adit being driven to tap the shaft at the Calliope mine is now in 825 ft. A 24-in. vein of \$17 ore is being opened in the upper workings. Tim Manion is in charge of the work.

SAN JUAN COUNTY.

The new tramway at the Gold King mine has been completed. Victor E. Kerr is manager.—Kunz & Reed have completed their contract for 500 ft. of drifts in the Precious Metals mine near Silverton and the company has advertised for bids for 2000 ft. more work.—A new vein with considerable zinc has been cut on the Arpad property. Seven Waugh drills have been installed in the mine and the mill is being repaired. Should the zinc content continue to any extent an electric separator will be installed in the mill. W. B. Lowe is manager.

SUMMIT COUNTY.

The plans for a 100-ton concentrating plant have been drawn and the material for its construction ordered by the Colorado-Toledo Mining Co. for the Colorado-Toledo mine at Montezuma. The adit is now in 1100 ft. and heavier machinery will be installed at the mine. At the Pennsylvania mine near Argentine the mill is being re-built and the mine further developed. W. B. LeWald is manager of both properties.

TELLER COUNTY.

A 75-ft. cross-cut from the 960-ft. level of the Trilby mine cut a vein assaying as high as \$90 per ton. The company is shipping a car of ore per day.—The Requa-Savage Gold Mining Co. declared a dividend of $\frac{1}{2}$ c. per share on July 31.—The John Sharpe Machine Works of Cripple Creek is installing a spray washer for Milhoan & Mart at their lease on Raven hill.—The Modoc Mining Co. shipped two cars of ore to the Colorado City mills.

IDAHO.

BLAINE COUNTY.

The mill of the Idaho Mines Consolidated, Ltd., has been completed. Some \$500,000 has been expended on the plant, which is built in two units, one for wet, the other for dry concentration. Both halves are handling 150 tons of tailing per day, the wet portion concentrating 10 to 1 and the dry 8 to 1. The process is a new one and aims at the separation of the lead and zinc content of the ore. The Minnie Moore shaft has been unwatered to the 900-ft. level and will be drained to the 1100 within the next 60 days. The drifts at that level will be re-timbered and stopes started on the vein. The property is situated four miles south of Halley.—The 100-ton mill of the Independence Mining Co. has been completed and is now making its initial run. It is operated by electric power.—The machinery for the mill of the Boston-Idaho Mining & Milling Co. on Boyle mountain has been forwarded to the mine and the mill will be in the course of erection within a short time.

IDAHO COUNTY.

The Big Baldy Mining Co. is re-opening the Old Judge mine, now called the Washington, in the Buffalo Hump district. Joseph Pelikan, of Spokane, is manager.

LATAH COUNTY.

A 14-ft. vein of free-milling ore was cut by the adit of the Gold Mountain Mining Co., operating in the Hoodoo district. James Baumgartner is in charge of the work.—The Mountain Gulch Mining & Milling Co. has a lot of ore on the dump ready for shipment.—The adit of the Gold Nugget Mining Co. is in 400 ft. and is expected to tap the vein at any time. A depth of 300 ft. on the vein will be attained.—A new shaft on the property of the Inland Empire Copper Co., near Deary, is down 60 ft. and an adit started that will cross-cut the vein at a depth of 200 ft.—Considerable work is being done on the Gemmill property near Inland.

NEZ PERCE COUNTY.

The trail from Lookout to the Bullion mine is being

widened and re-graded to facilitate the packing in of a new sinking pump. A drift is being driven on a vein of copper ore.

OWYHEE COUNTY.

An electric blower has been installed at the Banner adit. This is now in 1380 ft. and has cut some stringers of good ore. The management expects to cut the main orebody within the next 100 ft.—Arrangements have been made with Eastern capitalists to finance the Wennersten Mining Co., near Silver City. A cross-cut has been driven several hundred feet toward the vein. J. M. Morgan, the manager, has been in Boise City purchasing machinery for the mine.

SHOSHONE COUNTY.

The drift on the property of the Samson Mining Co. in the Murray district has opened a shoot of ore that assays 60% lead and 74 oz. silver per ton. A. J. Brainard, the manager, has purchased cars, rails, and other equipment for the mine.—The adit of the Pandora Mining Co., adjoining the Snowstorm mine, is in 960 ft. John Weatherhead is in charge of the work.—The mill at the Bear Top mine is running steadily on good ore from that mine. A carload of concentrate was shipped to the smelter recently.—The Vienna Vein Mining Co. on Placer creek has resumed operations and let a contract to drive 50 ft. on the vein. W. B. Lively is secretary of the company.—A diamond-drill has been installed on the lower level of the Great Western mine east of Burke.—The Rockford Mining Co. is to resume work on its property on the west fork of Big creek. John Furst is manager.—An order has been placed for 1000 ft. of air-pipe and lumber for buildings at the Blue Bell mine on Big creek. A lower adit is in 700 ft. and some excellent galena ore has been opened in the upper workings. Gus Nelson is manager.—A carload of galena ore from the H. E. M. mine in Revenue gulch was settled for on the basis of \$28 per ton. This ore came from the upper level of the mine. A cross-cut is being driven lower down that is now in 550 ft. and should tap the ore-shoot within the next 70 ft.—On the Black Bear fraction near Gem a 1300-ft. drift has been run from the face of a 2000-ft. adit. This has opened an 8-ft. shoot of galena ore. Peter Bernier is manager.—The Imperial Mining Co. has installed an electric-power plant at the mine southwest of Burke, and wires are being stretched to carry the current. A 2700-ft. cross-cut is being driven to tap the orebody being mined in the upper levels. John H. Nordquist is manager.

KANSAS.

CHEROKEE COUNTY.

The new work north of Galena on the Ping and Robertson leases has opened an orebody between 200 and 300 ft. A new 400-ton concentrating plant is to be erected on each lease, to be supplied by the three-compartment shaft which is on the dividing line.—The New Jersey Zinc Co. has found a deep run on the Murphy land north of Galena, corresponding closely to the Ping and Robertson and also the Herald deposits.—A new deposit of unusual richness has been uncovered recently on the Middlesex ground at Badger, where the ore occurs from 90 to 100 ft. A 10-ft. face is said to run about 30% blende.—The more recent prospective work in the Galena camp is the plan of Waterhouse & Co. to build a 300-ton mill on the Maggie Taylor tract.—The Mission mine in the Baxter Springs camp has been purchased by Deane Bros. The ground is well opened and a small concentrating plant is on the property. The '3 F.' mill has also been sold.

MICHIGAN.

The Oneco Copper Mining Co. is preparing to diamond-drill its ground to prospect for the Baltic lode.—The Keweenaw Copper is drilling the fifth hole to cut what is believed to be the Kearsarge lode. Four holes drilled by the company on this lode have shown a good copper content. When this hole is completed the drill will be moved to the Osceola lode.—All work at the Cliff branch of the Tamarack has ceased and the property is now idle. Work there was entirely in the nature of exploration. Underground operations extended over a period of three years, in which time the Old Cliff workings were unwatered to a

depth of 250 ft. and a total of 3500 ft. of drifts run.—Operations at the Old Colony, which have been entirely in the nature of underground explorations, have ceased, and the property is again idle. The exploratory campaign just closed extended over a period of six years, in which time the property was extensively diamond-drilled and a thorough investigation of the half-dozen copper-bearing lodes disclosed was made. The very encouraging showings obtained in the drill-cores did not result in equal encouragement in the opening of the orebodies by drifts and cross-cuts, and though several bunches of good ground and one or two very large pieces of mass-copper were opened, the larger portion of the ground was barren.

MONTANA.

DEERLODGE COUNTY.

A large body of hubnerite, a tungstate of manganese ore, has been discovered by Benjamin Danials on the crest of Sugar Loaf mountain, at the head of Race Track creek, near Anaconda.

LEWIS AND CLARK COUNTY.

Thomas Cruse has purchased the Belmont mine in the Marysville district. The Belmont adjoins the Bald Mountain mine, which Mr. Cruse is now operating, and is one of the properties which served to make Marysville famous as a mining camp. A mill is being erected at the Bald Mountain mine, and will be ready for operation early this month.

MISSOULA COUNTY.

The shaft of the Josephine mine in the Nine Mile district is down 150 ft. and a contract is to be let for 100 ft. additional work. The shaft is sunk in a gold-silver-copper ore.—The drift at the Alameda mine is being driven on a 7-in. vein of high-grade ore. Edward J. Johnson is manager.—The Butte & Couer d'Alene Mining Co. is running a drift on a vein of oxidized copper ore on its property one mile from Saltese.

NEVADA.

CLARK COUNTY.

The main shaft of the Oxnard-Eldorado mine is down 200 ft. and a station is being cut at that point. The shaft is sunk in the vein, which is 20 ft. wide. A. J. Peak is manager.—At the New York-Searchlight the shaft cut the orebody at a depth of 300 ft. As a heavy flow of water was found, new pumping machinery has been ordered, and the company will continue sinking as soon as this is installed. W. W. Hunt is manager.

ESMERALDA COUNTY.

The long-threatened war of the Yerington-D. O. Mills interests, through their Southern Development Co., upon the property-owners of the Luckyboy district, has been started by the service upon Ivan J. Enderson, owner of the Hard-scrabble group of claims, of a subpoena to appear before the United States Circuit Court at Carson City on September 6, in a hearing in which he is made the defendant. The Southern Development Co. claims the surface and mineral rights of the land in question, and alleges that it obtained these rights by purchase from the State of Nevada after the passage of the Act of March 7, 1879, by which the State obtained a grant of 2,000,000 acres of land from the United States Government. The suit filed against Enderson is in the nature of a test case, as the decision involved will affect the titles of many operators. At the time of the filing of the test suit at Carson, notices of trespass were sent to R. V. LeGrand and J. H. Miller, ordering them to cease all operations upon the ground in dispute and alleging trespass.—The plant of the Goldfield Chlorination Works is being repaired and will resume operations in the early part of September. Benjamin Hall, manager for the Pioneer Reduction Co. of Nevada City, has purchased the controlling interest and is superintending the repair work.—The shaft of the Atlanta cut a body of copper-gold-silver ore at a depth of 540 ft.—The Morrison lease on the Daisy ground is shipping 5 tons of ore per day.

HUMBOLDT COUNTY.

At National development work on Charleston hill is opening a number of veins of high-grade ore. On the Stall lease

a 10-ft. vein has been opened that assays from \$15 to \$60 per ton, with streaks of high-grade.

NYE COUNTY.

(Special Correspondence).—At the West End considerable work is going on at the 275 and 400-ft. levels. Steady shipments of good-grade ore are being maintained.—The Fenestemaker-Hurley lease on the Joker has cut a 5-in. stringer of ore running \$300 per ton at a depth of 10 ft.—The Jolly Jane lease is installing a 20-hp. hoist.—The shaft at the Sunnyside mine of the Round Mountain Co. is down 700 ft. and ore is coming from every level to the mill.—The Millet Mining Co. is developing a promising vein in the Brooklyn group. Assays run from \$50 to \$400 per ton. A smaller silver-lead vein also has been traced for 225 ft. on the property.

Tonopah, August 2.

The Sunnyside mill of the Round Mountain Mining Co. at Round Mountain is nearly completed. A new 5-drill compressor has been installed at the mine, and both mine and mill machinery will be operated by electric power. L. M. Louis is superintendent.—The suction dredge installed on the claims of H. C. McCallum and E. D. Nurse at Manhattan handled over 300 cu. yd. of gravel per day successfully in its initial run. The estimated cost of operation is 25c. per cubic yard.—On the 1000-ft. level of the Tonopah-Belmont the stope on the South vein is over 100 ft. long on an orebody that averages 5 ft. in width.—At the MacNamara a new compressor has been installed and is now furnishing power for the hoist as well as the drills. Stopes have been started on an 8-ft. orebody at the bottom of the winze from the 200-ft. level. This ore is sent to the smelter without sorting. Work is to be resumed at the 765-ft. level and the vein prospected at that point.—The foundations for the new mill at the Tonopah Extension are completed and work will be started on the steel work next week.—The raise from the 635-ft. level of the Midway has reached the level above, and the winze is down 60 ft. on a stringer of fair ore.

WHITE PINE COUNTY.

G. L. Richard has announced that the Ely-Calumet Mining Co. will open its property to lessees. The claims are crossed by a dike containing stringers of high-grade ore and larger bodies of low-grade material.

NEW MEXICO.

GRANT COUNTY.

The Golden Giant mine at Pinos Altos has been purchased by D. J. Hayden, George M. Masterson, and Alvan N. White. There are six claims in the group, which has been prospected by a 750-ft. shaft with drifts driven in ore at each 100-ft. level. Some 8000 tons have been shipped to the smelter, which averaged \$30 per ton. There is a 10-stamp mill on the property, which will be repaired and put in operation.

OREGON.

JACKSON COUNTY.

Work is to be resumed shortly on the Opp mine, near Jacksonville. Some 2000 ft. of drifts and cross-cuts have been run, that opened five veins of low-grade ore. There is a 20-stamp mill on the property which is in excellent condition.

UTAH.

BEAVER COUNTY.

Recent assays from the Beaver Lake mine assayed 60% copper and \$3 gold. The company has several tons of ore of this grade on the dump preparatory to shipment.—A winze is being sunk from the fourth to the fifth level of the Cedar-Talisman. A good shoot of ore was cut by the drift on the fourth level, and it is this that the winze is following. There are two types of ore in the mine, one lead-silver and the other zinc. S. S. Pond is manager.

JUAB COUNTY.

The lower adit of the Uncle Sam mine cut a body of shipping ore at a point giving several hundred feet of backs. The company is shipping seven cars of ore per week.—The shaft of the Zuma mine, in East Tintic, is down 265.

ft. in a limestone formation.—At the Eagle & Blue Bell mine the winze from the 1000-ft. level is opening a body of ore assaying well in silver.—The Gemini shipped two carloads of ore to the smelter.—A contract has been let to sink the Grey Rock shaft 100 feet.

SALT LAKE COUNTY.

The Silver Shield Mining & Milling Co. is planning to issue five and seven-year bonds to raise capital to build a 60-ton mill and concentrating plant at its mine in Bingham Canyon. There are 9500 ft. of development work on the property, blocking out 14,000 tons of ore. Harry S. Joseph is manager.

SUMMIT COUNTY.

The cross-cut from the 1200-ft. level of the Daly-Judge mine cut a vein of good milling grade, with which was associated a small amount of zinc. At present the company is stoping ore on a 10-ft. vein.—The Little Bell Mining Co. is opening a stope at the bottom of a winze sunk 200 ft. from the 700-ft. level. A tramway has been completed to the Daly West mill, and the ore now coming from the mine, together with the low-grade material on the dump, will be sent there for treatment. E. L. Talbot is superintendent.—Work has been resumed at the South Dakota mine. Frank Walker is superintendent.—On the Andes claim of the Silver King Coalition Mines Co. the winze from the 1100-ft. level opened a body of lead-silver ore at a depth of 540 ft. The ore assays 48% lead, 400 oz. silver, and \$4 gold per ton and is found on a contact.

WASHINGTON.

CHELAN COUNTY.

The Chelan Butte Gold Mining Co. shipped a car of high-grade ore to the smelter. The ore comes from the surface

Map of Washington.

workings of the mine. The Chelan Consolidated Mining Co. is developing a vein of copper-gold ore that is 12 ft. wide and assays from \$35 to \$50. Several veins have been cut by the company's adit.

FERRY COUNTY.

The Lucile Dreyfus mine near Danville is shipping a car of first-class ore per week to the Granby smelter.—Work is to be resumed on the Pearl Consolidated mine in the Republic district. This mine was formerly known as the Lone Pine, and ore shipped from this property approximated \$100 per ton.—The Ben Hur mine, which has been idle for six years, has been re-opened and a 5-ft. orebody cut. The high-grade material will be shipped to the Granby smelter.

KITTITAS COUNTY.

Samples from the outcrop on the property of A. F. York, in the Swank district, assay \$300 per ton.

OKANOGAN COUNTY.

The Duluth-Toroda Mining Co. purchased the Bodie mine, 12 miles southeast of Chesaw, for \$22,500. There is a 10-stamp mill and cyanide plant on the property. These will be put in good condition and a new road completed to Chesaw. The mine has been opened to the 400-ft. level and 60,000 tons of ore blocked out. Henry Thompson is in charge of the operations.—A contract for extensive de-

velopment work has been let by the management of the Methow Belle Mining Co., operating on Lookout mountain, south of the Alder mine.—The Alaska Riverbed Mining & Development Co., started operations with its machine August 1 on the Similkameen river. The management claims this machine will clean up from \$45,000 to \$50,000 per month at that position.—A crew of surveyors is working on the proposed line of the Okanogan Electric railway. As there are over 40 prospects along the route considerable activity is manifested in the mining district that will be directly benefited by reduced freight rates.

STEVENS COUNTY.

The Alladin Mining Co., operating near Northport, has completed a 4000-ft. flume and 50-ton concentrator. The company is developing a body of silver-lead ore that assays 30% lead, 20 oz. silver per ton, and a considerable amount of zinc.—A full equipment of machinery, consisting of pump, hoist, and boiler, has been purchased by the Imperial Copper Mining Co., operating in the copper belt near Chewelah. P. J. Bonner is superintendent.—The vein in the shaft of the Oriole Mining Co., operating in the Metaline district, has widened to 5 ft. at a depth of 60 ft. and assays \$40 per ton.

CANADA.

BRITISH COLUMBIA.

The British Columbia Copper Co. is to enlarge one of its furnaces at the Greenwood plant. They are now 56 in. wide by 20 ft. long. The company will add 10 ft. to the length, making it the largest furnace in the Dominion. The company will also resume work at its Mother Lode mine.—The properties of the Sullivan Mining Co. were sold by the sheriff at Cranbrook to satisfy a judgment of \$12,000. A mortgage of \$400,000 against the property has been settled, and it is reported that the properties will be worked by the Federal Mining & Smelting Co., with James Finlay as manager.—The mill and cyanide plant at the Jewell mine, near Greenwood, will be completed the early part of September. It is to be operated by electric power from the Bonnington Falls power line.—Considerable activity is manifest in the Sheep Creek district, 25 miles north of Nelson. At the Queen mine the 20-stamp mill is producing between \$15,000 and \$20,000 worth of bullion per month. The Kootenay Belle is opening a 2-ft. vein that averages \$90 per ton, and the Nugget is working in high-grade ore.

ONTARIO.

A 3-in. vein of calcite, with some cobalt and native silver, has been cut by the drift on the 125-ft. level of the Empire mine near Cobalt.—Another drill has been added to the equipment of the Beaver, and a winze started from the 200-ft. level.—An 8-in. vein of cobalt and silver has been opened by surface-cuts on the J. H. Waldman property. A company will be incorporated to develop the find.—Ore valued at \$3750 per ton has been found on the prospect of Robert Steen at Sturgeon lake.—The 3-in. vein on the Slaght claim in South Lorraine has widened to 12 in., all of which is rich enough to ship.—At the 125-ft. level of the Keeley mine a 6-in. vein of calcite, with cobalt and silver, has been opened.

MEXICO.

CHIHUAHUA.

The Compania Minera de Naica is to build a smelter at Conchos for the treatment of its lead-silver ores. The company owns the San Pedro and adjoining properties in the Naica mining district. The plant will handle custom ores to obtain flux for its own output.

JALISCO.

The main vein on the El Favor property in the Hostotipaquillo district has been cut by the company's transportation tunnel when in 750 ft. The vein at this point was 55 ft. wide.—A. H. Harrison has bonded the old Refugio mine for \$85,000.—An 18-in. vein assaying 1000 oz. silver and 13 oz. gold has been cut in the San Pablo mine, in the Etzatlan district.

SONORA.

Iowa capitalists have bonded the Veta Grande mine from N. S. Finch of Bisbee for \$50,000.

Special Correspondence.

LONDON.

East Pool Difficulties.—Cornish Versus Electric Pumps.—Damages.

The East Pool mine at Camborne, Cornwall, has for some time been in an unfortunate position, owing to the continual decrease in the tin content of the ore mined. Recently mining circles have been startled by a revelation relating to the mining methods pursued by those in authority, and the result is that many have to admit the shattering of an idol. It was commonly supposed that East Pool was well managed, and in spite of what is known now of underground methods it can still be stated that the re-modeling of the dressing plant and the provision of the necessary capital therefor out of revenue during the time that high prices ruled for tin showed an enlightened policy on the part of

have been allowed to drift. The pumping engine does not do its duty properly, and the coal bill is therefore too high. Also the pit-work connected with the pumping plant has been allowed to get into a very indifferent condition. But the chief point in connection with Mr. Thomas's criticism relates to the utter absence of exploration and development during the last few years. He states that the whole of the ore mined has come from old stopes that were left in previous years as unprofitable, and that no new ground has been opened. This lack of exploration in depth he attributes to the fact that the pumps were unable to reduce the water-level sufficiently. I should add as my own opinion that the provision of an ore-dressing plant capable of treating complex ores was one reason why the old stopes were re-opened. However, Mr. Thomas gives detailed advice as to the more efficient arrangement of the existing pumping plant, and makes several recommendations relating to exploration work. The mine is not at greater depth yet than 1500 ft., as compared with Dolcoath's 3000 ft., where some of the best

A Group of Cornish Tin Mines.

the directors. East Pool is a cost-book company, and it gained the distinction of not dividing its profits up to the hilt. The company has done good work in ore-dressing, and successfully tackled the problem of separating magnetically the wolfram from the tin, arsenic, and copper. In addition, the experiment with the high-speed air-cushion stamps has been worthy of notice. For some months it has been evident that the content of the ore mined has been decreasing, and the financial results for the last three quarters have been disastrous. In January and April deficits had to be met, and now a further loss of £3479 has been incurred during the quarter ended June 30. The amount of ore treated was 15,834 tons, and the average produce was 19.2 lb. of tin concentrate, together with some wolfram and arsenic. The revenue from the tin content was £11,388, from arsenic £843, and from wolfram £1240. The tin recovery during the three months previous was 20.8 lb. of concentrate per ton. This continued drop could not be allowed to go on forever, and the directors determined to seek outside advice. Accordingly, R. Arthur Thomas, of Dolcoath, was asked to examine the mine. His report has just been issued, and it is far from complimentary to the late management. His opinion is that things underground

ore in recent years has been found. As mentioned a few months ago in connection with the adjoining mine, South Crofty, the success in depth at Dolcoath should encourage the other Camborne mines to spend money in sinking deeper.

From time to time reference has been made in this column to the difficulties experienced by Cornish mines in connection with electric pumping. The old Cornish pump has the advantage of running automatically with little attendance. It is not subject to breakdowns, nor is it expensive in power and repairs. But it has its limits of usefulness, and when unwatering operations, or sinking to great depths, are contemplated, it has become necessary for Cornish managers to investigate the claims of modern electric pumps. Unfortunately, owing to mining men not understanding the intricacies of electric machinery, and the electrical engineers not being in touch with the requirements of a mine, many of the plants so far erected in Cornwall have been failures, and mutual recriminations have been plentiful. One of the most recent cases is that of Great Wheal Busy at Chacewater. This mine was acquired a couple of years ago by a French syndicate of chemical manufacturers who were desirous of obtaining an independent supply of arsenic. The

syndicate arranged with a prominent firm of manufacturers of electrical machinery in London for the supply of a pump. As is usual in contracts of this sort there was a penalty-clause providing for damages in case the pump was not delivered in working order by a certain date. The case was complicated by the contracting firm not supplying the pump itself, but sub-contracting to other firms. It is not surprising, therefore, that with all the ins and outs of contracts and sub-contracts the efficiency of the pump and its applicability to the work in hand was obscured. In the end, there was great delay in the delivery of the pump, and when it was erected it could not be made to do its work. Consequently the mine-owners discarded it and are now putting a Cornish pump in its place. They also brought an action for damages against the firm that supplied the pump, and judgment has been given in their favor. A sum of no less than £2700 has been awarded to the mine-owners for the delay and the failure to work. The moral to be drawn from this story is two-fold. To begin with, in new ventures of this sort the presence of intermediaries involved in contracts and sub-contracts is highly disadvantageous to the actual contracting parties. It is a pity that the people who want a pump, and the people who design and make it, cannot get together and discuss requirements and capacities. The second consideration is that the mining engineers and the electricians ought to meet and learn each other's experience. A mining engineer accustomed to a Cornish pump imagines that all pumps, even electric pumps, should work efficiently with just as little attention and study. On the other hand, the electrician designs a pump with little or no knowledge of the rough conditions existing in a mine, and expecting the mining engineers and miners to be qualified to take care of the delicate anatomy of an electrical machine. One might as well expect a mule driver to train a race horse.

BRITISH COLUMBIA.

Consolidation of Copper Companies.—Shipments and Developments.

It is now officially announced that the British Columbia Copper and New Dominion Copper companies will consolidate. This has been largely brought about by the Lewisohn interests, which own stock in both. The mines of the British Columbia Copper Co. are to be opened next week. The trouble with the miners has been adjusted, and coke is coming in rapidly. That the British Columbia Copper Co. expects to treat a greater tonnage from now on than it has in the past is evinced by the fact that they have begun to enlarge their copper furnaces, lengthening by 10 ft. the now 20 ft. by 56 in. furnace. It is likely that the other two furnaces, 20 ft. by 46 in., will be enlarged in turn.

The Little Bertha mine, on the North Fork, shipped a 30-ton car of select ore during the past week, this being the first lot of ore sent out from the Little Bertha so far this year. The Granby Consolidated M., S. & P. Co. is making preparation for the shipment of a heavy tonnage from the Monarch section of its property. Development has disclosed an immense body of good ore in Monarch ground. In the new workings full advantage will be taken of gravity, the ore being sent through the Gold Drop to the big crusher at the tracks, a distance of about 3000 ft. The Granby shipments for the week ending July 25 show an increase of nearly 2000 tons over the previous week, and it is expected the figures will gradually climb until the high record of 25,569 tons for the week ending February 13 will be exceeded. The Snowshoe shipments are also increasing.

It is expected that a mere matter of days will see work resumed at the Le Roi mine near Rossland, now that the managing director, Mr. McMillan, is here, having returned from a successful business trip to London. Those who know the mining conditions in this district feel sanguine that the plan of development proposed will develop extensive deposits of the rich ore that has already been found on the 1650-ft. level of the mine. Twenty tons of rich gold ore was shipped from the I. X. L. mine during the past week. The property is being worked on a small scale, but the history of the West Belt is that rich ground may be broken into any day, when things will pick up. The June

smelter receipts of the Le Roi No. 2, Ltd., were \$34,282. This property is shipping a monthly tonnage of 2400 tons of \$22 average ore and is paying dividends.

During the fiscal year ending June 30 the smelter and refinery of the Consolidated M. & S. Co. of Canada, at Trail, produced gold, silver, and copper, also lead, to the value of \$5,500,000. Over 42,000 tons more of ore were treated than during the previous year. The portion of the output credited to the electrolytic refinery is \$2,700,000. It is fully expected that the figures for the coming fiscal year will far exceed those of the past, as the mining situation in British Columbia, and particularly in southeastern British Columbia, never looked more favorable than at the present time.

NEW YORK.

Dredging for Diamonds.—Metal Exchange Rules.—Trading in Copper-Warrants.—International Smelting.—Steel Shares.

Capital is being sought in New York for new plants to dredge for diamonds on the Jequitinhonha river in Brazil. Diamond-mining leases have been secured by Brazilian corporations promoted by American citizens for washing diamonds over several hundred miles of the river and its tributaries. The corporations propose to sub-lease their rights for one-third of the value of the products won by the dredges, provided a dredge is operated on every mile of river that is sub-leased. This method of sub-leasing has been developed lately in the vicinity of the city of Diamantina. About half a dozen small dredges are now operating on the Jequitinhonha. Most of them are of the bucket type, but as the river-bed, in places, is rough and stony, pump dredges have been installed. In addition to diamonds, gold, platinum and the platinum-metals, and numerous other gem-stones occur in the wash. It has been demonstrated that the dredging method of recovering the gems is in advance of the old Portuguese practice of washing and sluicing by hand. There is a good fall in the river above the city of Diamantina, where the chief dredging-claims are situated, and advantage is taken of the current to generate electric power. Most of the dredges are operated by electricity. No dredge has been able to much more than pay expenses. Some of the promoters of new dredging schemes, however, are circulating reports of great profits to the dredge-owners. These are likely to mislead investors, and it should be said that American investors should be careful to thoroughly investigate Brazilian diamond-mining propositions brought to their attention before acquiring interest in them. The United States Consulate at Rio de Janeiro is well informed upon the diamond-mining industries and will furnish particulars to investors.

The new rules of the New York Metal Exchange, which took effect on August 2, brought the business practice of the Exchange into conformity with that of the London Metal Exchange. A large amount of the business on the London Exchange is of a purely speculative character. Copper-warrants, for example, are traded in daily in a similar way to the wheat-trading in the Chicago wheat-pit. This kind of trading was not popular under the old rules of the New York Metal Exchange. Whatever trading in copper-warrants and 'futures' was done in this City was done through London brokerage houses. It is probable that the leaders of copper production will endeavor to make trading in copper popular in New York, in order to enable them to more easily manipulate the price of the metal. Steps are now being taken to start the business in a small way on the New York Metal Exchange. Copper ranks sixth in the list of speculative commodities, in respect to value—corn ranking first, with a value about 12 times that of the copper yield, cotton second, hay third, wheat, with a value of about 6 times that of copper, fourth, oats, valued at 3 times as much as copper, fifth, and copper sixth. The trading in futures in other commodities is world-wide, and some of the New York brokerage houses are asking why not trade in copper too. At present trading in copper-warrants is almost confined to London.

The meeting of the directors of the International Smelting Co., which was scheduled for July, and at which a divi-

dend was expected to be declared, was not held on account of a quorum being unobtainable. This has been widely commented on, and it is reported that the cause of the failure of the directors to meet was the condition of the stock market. The market being dull it was thought inopportune to have the stock listed on the Exchange in July. The company's earnings available for dividends are at present running at the rate of 12%. The directors will meet within a couple of weeks. It is probable that a 5% dividend will be declared, and steps taken to have the company's stock listed on the New York Stock Exchange.

The directors of the United States Steel Corporation at their last meeting reported that the steel business is gradually improving, and that the company's prospects are good. Tariff manipulation has enabled the company to advance the prices of steel products, and the prospects of increased returns have enabled the directors to increase the dividend from 2 to 3% per annum. Before declaring the increased dividend the price of the company's common stock was advanced from 42 to 72 $\frac{1}{4}$ %. The Exchange manipulation of the stock was carried out by an important New York bank working in co-operation with a powerful financial pool which operates extensively on the New York Stock Exchange in the stocks of many of the large copper mining and smelting companies, as well as in those of the United States Steel Corporation. Owing to the reputation of steel common stock the pool found it an expensive matter to advance the price of the stock. They succeeded, however, in distributing a large amount of it acquired around 30 and 40 at from 60 to 72. As soon as the whole of their holdings are distributed attention will be given to the distribution of the pool's holdings in copper and smelting companies. Copper stocks generally will, doubtless, advance in sympathy with the pool's operations in the stocks of companies it controls.

MEXICO.

La Blanca Purchase. — Santa Gertrudis Bonded. — Coneto District, Durango. — Balsas River Copper. — Oaxaca. — Hidalgo. — Hostotipaquillo.

The examination of La Blanca mine at Pachuca, Hidalgo, by John Hays Hammond and his engineers has been completed, and there is little doubt that the deal will be carried through. José V. de Landeros y Cos, president of the Santa Gertrudis y Anexas, which adjoins La Blanca, is quoted as stating that an option has been given Mr. Hammond on that property, and the figures are placed at \$9,000,000, or \$150 per share for the 60,000 shares. The Santa Gertrudis is one of the largest and richest of the Pachuca properties, and would be most desirable in connection with La Blanca for the organization of a large company and the economical working of both properties combined. There is no reason to doubt, therefore, that negotiations may be on for the purchase of the Santa Gertrudis, but there is certainly some mistake made in the price named, for the stock is selling on the market in Mexico City at \$116 to \$120, and there has been no rise in the price since it was reported that a sale was being negotiated; hence the figure of \$150 per share may be looked upon as high.

From the State of Durango come reports of rich discoveries in the old Strauss mine, in the Coneto district, now being operated by the Eva Mining Co.; the strikes were made in what are supposed to be old Spanish workings, and a number of rich veins are being uncovered. The Coahuila Mining & Smelting Co. is said to have found high-grade silver ore in the Alberto mine in the Mapimí district. The San Juan Mining Co., also of the Mapimí district, is shipping at the rate of 100 tons of ore per day, and at the same time is putting in new machinery to enlarge the output. This company is also planning to run its own railroad to Bermejillo, to connect with the Mexican Central, as the narrow-gauge now operating between Bermejillo and Mapimí is a private road of the Penoles Mining Co. It is not probable that very favorable terms, if any at all, could be obtained by an outside company that did not wish to ship to the Penoles smelter at Mapimí.

In Guerrero the Maine & Nebraska Mining & Smelting

Co. is planning to build a railroad to its mines on the Balsas river, and also to erect a 100-ton smelter. The Marian and Helen Reese, continuations of the Maine & Nebraska holdings, have been taken up by R. R. Robertson of San Francisco, and he will soon begin operation on these properties. Those familiar with this part of Mexico, on both sides of the river Balsas, in the States of Guerrero and Michoacan, unite in stating that some of the most wonderful deposits of copper in the world are situated there, and that it but awaits the facilitation of the railroad to surpass anything now known in Mexico in the production of that metal.

In Oaxaca the Indiana-Oaxaca Mining Co. has completed its tests and will proceed with the erection of a mill, and at the junction of the Parada and San Pablo rivers a 250-hp. hydro-electric plant will be placed for the generation of power for the mine and mill. At the Victoria-Tapada a tunnel has been started to cut the Victoria shaft at the 320-ft. level. Prospecting continues, and the mill is in

On the Trail.

course of construction. The concentration and amalgamation mill of the San José de Gracia, in the Sierra Juarez district, has not proved satisfactory. Changes will be made, a cyanide plant added, and probably the whole thing enlarged. In the San Juan, of Taviche, the bonanza ore that was found some weeks ago in the second level has been opened on the third level, and has added greatly to the expectations from the property. Need of a railroad from Mexico City to the Pacific is being agitated, and it is stated that the Mexican-American Holding Co., with \$40,000,000 capital, has been organized for its construction.

The work of the Seguranza Mining Co. in Zacualpán, Hidalgo, has awakened J. C. Mordough and associates of Mexico City to the possibilities of their old Socavón, and they have refused \$100,000 offered for it by the Seguranza company, and will start operations upon it themselves. At Zimapán, about 75 miles west of Zacualpán, but also in the State of Hidalgo, the Zimapán Mining & Smelting Co., in the last ten months has opened large bodies of ore in the San Francisco and Los Balcones; and extensive development is being carried on in the Flojonales by the R. S. Towne interests, and on the properties of the Hidalgo Consolidated Copper Co. by the Ludlow brothers.

The Mina Grande and Quebradillas, old Spanish properties in Hostotipaquillo, Jalisco, have been taken over by Luis Cherrillan and French associates, and extensive operations will at once be started. The new tunnel of El Favor has cut the vein at a depth of 750 ft., where it is said the

vein shows a width of 58 ft.; and in the San Pablo, at Etzatlán, operated by the El Favor people, an 18-in. vein, assaying several hundred ounces in silver and 5 oz. in gold, has been found. The Zapote, in the Magistral district, near Ameca, is temporarily shut down, while a new hoisting and pumping plant is being installed. The Buena Fé Mining Co., at Ojuelos, Jalisco, is putting in a gas-producer, and gas-engine for electric pumps, air-compressor, and a gas-engine hoist, and a stamp-mill is being planned as a year's supply of ore is blocked out.

BUTTE, MONTANA.

Heavy Litigation Brewing.—Johannesburg Gold Mining Company.—San Felipe Mine.—Bamar Company.

The copper production of the Butte mining companies for July aggregated 26,580,820 lb., an increase over June of a little more than 1,000,000 lb. The totals, figured on the basis of 29 working days for July, are as follows:

| Companies. | Tons daily. | Copper, lb. | Tons monthly. | Output, lb. |
|-----------------------|----------------|----------------|------------------|----------------|
| Boston & Montana.... | 3,520 | 264,000 | 102,080 | 7,656,000 |
| Anaconda | 3,610 | 227,430 | 104,690 | 6,595,470 |
| Butte & Boston | 650 | 40,950 | 18,950 | 1,187,550 |
| Washoe | 550 | 33,550 | 15,950 | 972,950 |
| Parrot | 400 | 23,200 | 11,600 | 672,800 |
| Trenton | 410 | 24,600 | 11,890 | 713,400 |
| North Butte | 1,400 | 119,000 | 40,600 | 3,451,000 |
| Butte Coalition | 1,350 | 102,600 | 39,150 | 2,975,400 |
| Original | 610 | 45,750 | 17,690 | 1,326,750 |
| East Butte | 400 | 28,000 | 11,600 | 812,000 |
| Miscellaneous | 100 | 7,500 | 2,900 | 217,500 |
| Totals | 13,000 | 916,580 | 377,000 | 26,580,820 |

Strife is said to have been brewing for over a year between the Amalgamated Copper Co. and W. A. Clark. The trouble arises from a dispute over the metes and bounds of veins. The big company, it is understood, claims the veins within prescribed bounds, and so does Clark. The mines of the claims adjoin, and the issue, according to rumors is whether or not Clark shall follow the orebodies outside the lines of his claim. This is an old difficulty at Butte, and Clark and the Amalgamated companies have clashed before over the same thing. It has produced litigation, in which Heinze and others have figured. This new wrangle recalls that the Amalgamated several years ago opened negotiations with Clark for the purchase of his properties at Butte, but the deal was never consummated. It is said on good authority that Clark once was asked to name his price, and complied. He was invited to come to New York and close the deal, and he started for the metropolis for that purpose, but on the way he raised his price ten millions, and the Amalgamated backed out.

When Clark was proprietor of the Colusa-Parrot mine, one of the Anaconda hill properties, he was accused of mining his ores from Anaconda territory. An injunction and damage suit resulted, and it was decided against him. The Anaconda company recovered heavy damages, and in the settlement of the case the Colusa-Parrot mine was turned over to the company. It is understood that Clark's right to mine below the 1200-ft. level is questioned, yet he is mining at a depth of 2000 ft. or more. The public is unacquainted with the details of the dispute, and is in ignorance of just what veins are involved, but it is stated that Clark has been served with legal notice to stop mining beyond specified boundaries. He has disregarded the notice, which makes it probable that he will give the Amalgamated company a fight.

Andrew Nelson, general manager of the big gold mine of the Johannesburg Gold Mining Co. at Neihart, Montana, who was here recently buying pumping machinery, declares that the company has the biggest gold mine in the country. He was the discoverer, and has been working for five years, the past two years being manager of the company. The mine has a vein 40 ft. wide on the surface, which has been developed continuously for more than a mile.

The new machinery, including an Ottumwa engine and a 100-hp. boiler, bought by Mr. Nelson, will be installed at

once. The 200-ft. level cross-cut has a fine showing. The company is capitalized for 300,000 shares at \$3 per share, and \$120,000 was put in the treasury during the hard times recently by the sale of 120,000 shares of the stock at \$1 per share.

The Cole-Ryan people are said to have purchased the San Felipe copper mines, in the Arizpe district, Sonora, Mexico. They belonged to P. Sandoval, of Nogales, Arizona, and John Henderson, of Pasadena, California. It is reported that they paid \$400,000 for them. The group contains seven mines. It is said that active development will follow the purchase. The Cole-Ryan people are having trouble with a mining investment in Mexico, near San Antonio de la Huerta. They have spent large sums of money developing the San Antonio copper mines there. Recently an Arizona engineer named R. L. Hogue took up a portion of the ground, declaring it had been left open by a defective survey, and it is understood that the copper people will fight for the title.

Increased activity in the development of an old copper property within 10 miles of Butte is a recent event. Omaha and Butte capitalists and mining men have organized the Bamar Copper Co., capitalized for \$1,500,000, and it has taken hold of the Erick Rehn mine on the Oregon Short Line road. The Bamar company has contracted for the construction of a shaft on the Rehn mine to the 500-ft. level. There is a good copper vein in the Linda claim of the mine developed by tunnel, and the company is making a raise to the surface from the main tunnel, a distance of 116 ft. When this is finished sinking below the tunnel will follow.

JOHANNESBURG, TRANSVAAL.

State Mining Scheme.—Stope-Drill Competition.—A 'Black Reef' Fiasco.—Rand Profits.—Half Yearly Dividends.—Cloverfield Shaft Assays.

The Transvaal Government has taken a most daring and original step into a new field of political economy. Since the war it has received in direct taxation about 8½% (10% with certain allowances deducted) of the profits of gold mining. More recently it has been negotiating with the mines to increase its interest by the sale of the mining rights below water-rights, dumping sites, stands, etc., reserved to the Crown. Now it has gone a stage farther and called for tenders for the establishment of State mines. Two large Government areas in the East Rand—deep-level ground near the Modderfontein Deep Levels Co.—are offered for leasing. The lessee of each area will have to put up in cash £350,000, estimated to be required for shaft-sinking and preliminary development, and to guarantee a further £350,000 to bring the property to a producing stage. Clearly then, the proposition is not one for 'small fry' to consider. It is stipulated that 25% of the preliminary capital required must be offered for subscription to persons resident in the Transvaal. The Government provides no capital, and consequently takes no risk in the undertaking. It is further stipulated that no vendors', promoters', or founders' shares shall be created, and that no commission or underwriting will be allowed. The profits accruing to the State will be determined on a sliding scale, ranging from the present minimum of 10% (as affecting all other mines) up to 50%. Within these limits, the State is to receive the same percentage of the profits as the profits are of the total yield. For example, if the yield is \$8 per ton and the profit is \$4, the Government would receive \$2 on its maximum of 50%. Upon exhaustion of the mine, the Government is to receive 10% of the proceeds from the disposal of plant, etc., but this consideration is of small moment, considering the probably long life of the areas under notice. One of these includes 1275 claims and the other 1358 (one claim being 64,025 sq. ft.) Assuming there are 15,000 payable milling tons per claim, the contents of the areas will each be about 20,000,000 tons, giving a probable life of 30 to 40 years.

Some figures made public by the management of the Stope-Drill Competition show that there has been a marked falling off in the efficiency of the machines as the effects of wear and tear have become more conspicuous, and also

an increase in the air-consumption. Tabulated comparisons of drilling speed and air-consumption stand as follows:

| Machine. | In. per Min. | | Cu. Ft. per Min. | |
|---------------------|-------------------|----------------|-------------------|----------------|
| | Elimi- nation. | June 17-22. | Elimi- nation. | June 17-22. |
| Chersen | 4.11 | 3.27 | 81.8 | 84.5 |
| Siskol | 4.46 | 2.59 | 74.2 | 78.2 |
| Climax Imperial .. | 3.52 | 3.03 | 68.5 | 85.2 |
| Konomax | 2.48 | 1.73 | 29.6 | 33.15 |
| New Century 00 .. | 2.33 | 2.19 | 53.4 | 65.6 |
| Holman 2 3/4 in.... | 3.12 | 2.47 | 99.9 | 33.5 |
| Holman 2 1/4 in.... | 2.40 | 1.85 | 75.1 | 69.8 |

Broadly speaking, the drilling speed underground now appears about 25% less than that recorded in the first elimination trials.

For a long time past, the history of Rand mining and finance has been happily free from 'ugly incidents'. It seems to be in the distant past that we experienced the disgrace which fell upon the credit of lesser mining houses through the deception of the public by the 'riches' of the Vlaklaagte tin farm, the booming of the Vaal river diamond diggings, the salting of Madagascar gold alluvial, and the announcement of false assay results from the Geduld shaft. Lately, however, another unpleasant affair has occurred, by which the public has lost much cash and a directorate all credit. Out in the far West Rand there are several farms which,

negligible. Its rise into greater favor might have resulted in a far more serious fiasco than the bursting of the Midas Deep bubble.

Some interesting and valuable experiments are now being conducted upon the Langlaagte Estate, Robinson, and other mines, with a view to still further increasing the crushing capacities of existing batteries. At a later date, I hope to be able to go into further detail, but at the moment it may be said that the ideas being developed are (1) the practicability of washing out, through screens, the sand and slime from the crushed ore before it is fed into the mortar box, and (2) the diversion of the pulp from the boxes to the other tables when the plates are being scraped and dressed. In the removal of the sand, a screen is used of similar mesh to that in the boxes, so that there is no wasteful charging of the boxes with a product already sufficiently finely pulverized for treatment. It is estimated that the undersize will be equivalent to 7 or 8% of the mill tonnage, and this elimination of this amount will certainly enable the stamp-duty to be raised substantially. The saving effected by the diversion of the pulp from the plates while dressing is in progress, instead of stopping the stamps, would probably mean an increase of about 2% in crushing capacity. During recent months of ample labor supply, the commonest cause for complaint upon the mines has been insufficiency of crushing plant rather than any difficulty in keeping the bins supplied with ore. But in the winter months the periodical shortage of labor may reduce the benefits of such schemes for the increase of stamp duties.

The rate of profit-realization has not been increasing rapidly upon the Rand during the past few months, though, if labor is forthcoming, it will show a big rise toward the close of the year. During the first five months of 1909, the returns have been for the whole Transvaal as given below: (Rand profits equal 98% of the total.)

| | Tons milled. | Yield. | Profit. |
|----------------|--------------|-------------|------------|
| January | 1,647,895 | £2,612,836 | £1,047,395 |
| February | 1,539,270 | 2,400,892 | 944,262 |
| March | 1,719,758 | 2,580,498 | 994,038 |
| April | 1,693,234 | 2,578,804 | 1,019,288 |
| May | 1,765,048 | 2,652,699 | 1,038,292 |
| Total | 8,365,205 | £12,825,729 | £5,043,275 |

From these figures it appears that 40% of the gold output is profit or that it is costing about 12s. to produce a sovereign's worth of gold. The dividend-payers are now making their yearly distributions and forty companies have so far announced an aggregate of £4,528,895, which compares favorably with the total for the corresponding period of last year.

The Main Reef in the East Rand basin has been cut by another shaft. The vertical shaft of the Cloverfield Mines intersected the Reef at about 2000 ft., and samples round the perimeter averaged 22.3 dwt. over 10 in. or 6.5 dwt. over an assumed stoping width of 36 in. The sections sampled show the variations characteristic of this region.

TORONTO, CANADA.

Cobalt Stocks and Developments. — Nova Scotia Mill. — Provincial Mine.—Gillies Limit.—Montreal River.—Elk Lake.

Interest in the Cobalt stock-market, which usually subsides on the approach of the dog-days, has been kept alive this season by a succession of discoveries affecting a number of the lower-priced issues. While there has been no sensational rise in values, there has been much activity in trading with a general upward tendency. A new find on the Beaver was made last week consisting of a smaltite and calcite vein struck at the 200-ft. level. It is from 14 to 18 in. wide and is stated to assay 9178 oz. silver per ton. The shares rose from 28 to over 40 on the announcement of this discovery, but have since dropped a few points. Nova Scotia is another of the non-dividend payers which has experienced a boost owing to a succession of finds, the first and most important of which, known as the 'Bilsky' vein, was struck on July 2 on the surface, and showed 4 to 6 in. of rich ore. It has since been uncovered for 225 ft. and

Street Scene in Johannesburg.

admittedly, are 'possible' Main Reef propositions. Their possibilities, however, are hidden by the overlying younger formations—the dolomite and Black Reef. The latter is a pyritic conglomerate closely resembling the Main Reef series, but the gold content is notoriously patchy—large stretches being barren and pockets running up to 100 oz. or more of fine-gold per ton. One of these Black Reef (cum-possible Main Reef) properties is held by the Midas Deep company, which recently re-started work upon the Black Reef. Shares were put up to \$8.25 on the strength of semi-official reports of a 10-dwt. grade being maintained. Two months' milling, however, gave an actual extraction of about 5 dwt. An investigation made by A. Heymann disclosed the rankest mismanagement at the mine, and an erroneous estimate of grade and extraction to have been made. The assaying at the mine was being done, in a place adjoining the extractor-house, by the cyanide manager while working a 12-hour shift. Results were quite misleading, and instead of a rich mine of high average grade, the Midas Deep is shown to be a characteristically poor mine which has contained some remarkably rich pockets. Of course, the shares collapsed (to \$2) and there have been angry demands for Government enquiries and other drastic proceedings. Those of the public who have been spectators have good reason to rejoice at the occurrence. If the Midas Deep, by means of its rich pocket, had been able to maintain an average grade of 10 dwt. for a few months, there was danger of a Black Reef 'boom'. This conglomerate covers vast areas of the Transvaal, is easily explored, and is able to yield those occasional abnormally high assays so dear to the heart of the unscrupulous manipulator. Generally speaking, its possibilities for company working are

found to maintain its quality. Excavations are being made on this property for the installation of a 100-ton compressor and a mill for treatment by cyanidation and amalgamation. It is expected that 92% of the silver will be saved. The plant will cost \$100,000. A shaft is going down on the new Blisky vein at a point where it intersects other veins, and an adit will be run to tap the vein at 110 ft. from No. 1 shaft. At the Hargrave a calcite vein varying from 3 to 7 in. wide has been struck in trenching near the Kerr Lake line and has been uncovered for 150 ft. Native silver is exposed for 30 ft. of the distance. This vein runs into the Kerr Lake property. The Cobalt Lake recently struck a 2½-in. vein at 195 ft., which was found in a cross-cut from the winze at the 110-ft. level at the southern end of the lake. The silver content is stated at 5000 oz. per ton. The City of Cobalt recently opened a new vein in a cross-cut at the 140-ft. level which, though quite narrow at first, widened to about 5 in., the ore running about 4000 oz. silver per ton. At the Kerr Lake, No. 7 vein on being cut at the 210-ft. level was found to maintain its value. Seven veins, on all of which large quantities of high-grade ore are blocked out, have been opened. The Coniagas has passed the dividend of 3% expected on August 1, the directors assigning as a reason the need of accumulating funds for doubling the capacity of the concentrating mill and equipping the mill with electric power. The announcement was followed by a slump in the stock, which dropped to \$5.25, nearly a dollar less than the price of the previous day, but afterward rallied slightly. Vein No. 64 of the Nipissing, which has proved a rich producer on the upper levels, has been struck at a depth of 250 ft., where it shows niccolite and argentite. Shipments of ore have been fairly well kept up lately, though the consignments of the last two weeks, totaling 917 tons, look comparatively small beside the record-breaking output of the preceding few weeks. Nipissing was well to the front with a total of 228 tons, Crown Reserve coming next with 153 tons. The Provincial mine, no news of which has been forthcoming for months, has at last been heard of again. It is announced that a new vein has been struck by diamond-drilling at a depth of 265 ft., close to the old workings. Another sale by tender has been made by the Ontario Government of lots in the Gillies Limit, concerning the value of which everybody, apparently, including the Government officials, is entirely in the dark. A number of the lots offered before which were left unsold because the tenders were too low were again submitted to competition, and 201 acres disposed of for an aggregate amount of \$47,204, or an average of \$225 per acre. As the sale is subject to working conditions and payment of a royalty, the vexed question as to whether there really is any valuable mineral in the locality is likely to be settled before long. The Ontario Bureau of Mines has issued a statement showing the metallic output of the Provincial mines and works for the first three months of the year. There is a decided gain all round, especially in silver, the output of which was 5,628,860 oz., valued at \$2,648,852, as against 3,673,047 oz., of the value of \$1,938,840 for the corresponding period of 1908.

The White Reserve mine, in the Montreal River district, appears to be making good. Development has been going on since April of last year, and 240 bags of ore stated to average 5000 oz. silver per ton has been mined. Thirty veins have been uncovered, nine of them showing native silver. The main shaft is down 150 ft. On the Gavin Hamilton, in the Elk Lake district, vein No. 5 at a depth of 110 ft. includes 3 in. of ore running 6000 oz. per ton. On No. 4 vein native silver is exposed at the surface. The Cleaves claim, another well known Elk Lake prospect, which contains about 50 calcite veins, several of which contain silver, has been bought for the Beacon Consolidated Mines of Boston. Active development work is being begun at the Welsh claims, Gowganda, which adjoin the much-advertised Bartlett mine, under C. H. Rogers, an English mining engineer who has had South African experience. The Nancy Helen, which has been in hard luck lately, has leased half of its northern 40 acres to S. D. Madden, under conditions which call for immediate development work and active prospecting.

DENVER, COLORADO.

Coal Trade.—Clear Creek News.—Boulder Oil and Tungsten Producers.—Cripple Creek.—Coal and Asphaltum in Wyoming.

Unusual activity along all lines of industry causes the coal trade to be very good for this season of the year. The Suffield mine of the Green Canyon Coal Co., near Trinidad, has been re-opened to supply the local market. The Colorado Fuel & Iron Co. is unable to get enough miners and coke pullers, and has had to bring in outside labor.

There has been a steady increase in production from the Clear Creek district during the last six months. The record of the Chamberlain-Dillingham Ore Buying Co. shows that 40% more ore has been marketed than in the similar period in 1908. The mines and mills of the district are working steadily, and there is a feeling of assurance regarding the success of the new smelter at Utah Junction. Ore is now being piled at this plant preparatory to starting up about August 1. The North American Smelter & Mines Co. is also in the market for ores from this district. It has the old Golden smelter almost ready to start, and has signed ore contracts with several of the mines. The company has just made a bond issue of \$500,000, which is backed by a mortgage on the Donaldson and Centurian group of mines near Idaho Springs. The Newhouse tunnel is in 20,000 ft. and steadily advancing into Quartz hill. A new vein was cut during the past week. It is believed to be the Burroughs vein. A peculiar feature in this tunnel-development project is that no water-courses of note have been found, and now it will be necessary to do considerable driving, and either raising or boring, to tap the water in the mines to be drained. The Federal Trust Co. of Massachusetts has begun foreclosure proceedings against the Gunnell Mines & Milling Co. for \$566,000 on first-mortgage bonds. The property involved includes that of the Gunnell, Grand Army, Fagan, Star of Hope, and Slaughter House Lode Mining companies, together with ground in Central City, Eureka, and Black Hawk.

The Boulder-Greely Oil Co., drilling in the Boulder oil-field, has brought in another oil-well. Oil was found at 1800 ft. and rose 500 ft. at once. A pump is being installed. The tungsten industry in Boulder county is not as active as usual. The operators are waiting to be sure what protective duty will be put on the ore in the new tariff schedule. Should the 15% duty proposed in the Senate by S. Gugenheim be adopted, the Primose company will erect a new mill on the Boulder county ranch, and the Wolf Tongue Mining Co., at Nederland will re-model and enlarge its mill.

The recent strike in Dead Ox gulch, about three miles west of Cripple Creek, has caused a great deal of prospecting to be done on the ranches in that part of the district. The Red Cloud Mining & Prospecting Co. has been encouraged by the find, and has advertised for bids for driving an adit 400 ft. and sinking a shaft 100 ft. on its property on Mount Ervey, three miles southwest of Cripple Creek. The bids are to be opened August 5. The Eclipse claim belonging to the New Haven Gold Mining Co. has been sold to the Joe Dandy Mining Co. for a stock consideration. This action settles the dispute over the apex rights of this claim. The five patented claims on Ironclad hill belonging to the Lincoln Mining & Milling Co. have been thrown open to lessees. Another aerial tram is about to be put in operation in the district. It will carry the ore from the Midget mine on Gold hill to the Gold Issue mill on Carbonate hill, two miles distant. A small labor war was precipitated recently by the contractors on the grading for the new Portland mill importing Italian laborers for the work. The Italians were run out of camp and one shot in the ensuing fracas.

The Interior Department has just finished classifying and returned to the public domain a large tract of land in the Evanston district, Wyoming. This tract is valuable coal land and had been secured from the Government by fraud. As the outcome of the Horse Thief Canyon cases, the offending coal company was forced to re-convey the land to the Government and pay \$40,000 for the coal extracted. A large bed of asphaltum is reported to have been found on the Shoshone Indian Reservation near Landers, Wyoming.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Felsitic or aphanitic forms of grano-diorite and monzonite have been called pantellerite and vulsinite. The former has been applied chiefly to such rocks on the more acidic extreme, that is, to the felsitic variety of grano-diorite.

Hydraulic pressed brick stands fire well. In tests made at the underwriters laboratory in Chicago, no damage was apparent after firing and before water was applied. Although a number of bricks cracked, 70% was found sound after quenching with water.

Lithium is widely distributed among igneous rocks, but in small amounts. It may be detected spectroscopically in samples from almost any volcanic rock, but its more common association is with granites and pegmatites, occurring in spodumene, lepidolite, amblygonite, and in some tourmalines. It is generally associated with soda rather than with potash.

Gypsum is not in large demand for any purpose in a crude state. It is converted into land-plaster, plaster of paris, and into hard finishing plasters, in which form it has a steady market. The deposits are sufficiently abundant so as to necessitate, first, that they be found in large bodies, convenient for economical mining, and second that they be situated favorably for access to market, else they would possess little commercial importance.

'**Lime spar**', as calcite is sometimes called, occurs frequently in veins, and often constitutes the entire gangue of an ore. It has no significance as an indicator of metals. It is not uncommon as an accompaniment of gold veins in the desert region of the Southwest, and gives evidence that the portion of the vein where it occurs was not deposited at a great depth below the surface, as calcite will not form except at moderate temperatures and pressures.

Talc is a hydrous silicate of magnesia. It is generally foliated, but may be fibrous. The laminae are flexible but not elastic. Its most distinctive physical features are its softness, it being easily impressed by the finger-nail, and its greasy, soapy feel. It is practically infusible, is not decomposed by ordinary acids, and is a good non-conductor of heat and electricity. When highly heated it loses a small amount of water, hardens, and is susceptible to polish. It varies in color from apple green to white.

Radium rays manifest their energy by their capacity for exciting the luminosity of various phosphorescent substances. Radium salts are themselves luminous. Radium disengages continuously a substance which behaves like a gaseous radio-active material, called the 'emanation'. Air which has been in contact with a solution of radium salts is charged with the emanation, and it becomes a strong conductor of electricity. The emanation is an unstable gas, and spontaneously disappears, even from a sealed glass tube. It possesses the property of imparting radio-

activity to all bodies in contact with it, such bodies being then said to possess induced radio-activity.

Asbestos is used for a constantly increasing variety of purposes in fireproofing and insulating. One of the notable applications in recent years is as a pigment under the name 'asbestine', which on account of its fibrous structure has the property of holding up other heavier pigments in the paint. Mixtures of asbestos with various compounds play an important part in fireproof construction. Such materials are asbestos building lumber, century shingles, asbestos slate, asbestic for stucco and plaster, and asbestolith.

Peat cannot be dried economically by artificial heat alone. Assuming that a drained bog contains 12½% dry peat substance, the wet peat contains 87½ lb. water. If 80% of the fuel value be utilized, 1100 B. T. U. are required to evaporate 1 lb. of water, and dry peat has a calorific value of 9000 B. T. U. In order to evaporate the water, therefore, there is required 87.5 times 1100 divided by 80% of 9000, or 13.3 lb., of dry peat substance, which is more than is contained in the peat.

Chromite is of value as a source of chromium, being the only mineral of commercial importance in which that element is found. The uses of chromium are metallurgical, in the manufacture of alloys and furnace linings, and chemical, as a constituent in coloring materials, mordants, oxidizing agents, and tannages. Chromium gives to steel a marked degree of hardness, and, if added in the proper proportion, does not produce brittleness. Chromium steel alone or alloyed with tungsten or molybdenum is used in the manufacture of high-speed tools, and alloyed with nickel or manganese is used in files, ball-bearings, armor-plates, and armor-piercing projectiles.

Vesuvius emits a lava containing about 48% silica, 18 alumina, 7.6 iron oxide (FeO), 9 calcium oxide, and 7 potash, being thus remarkable for its high potassic content. The amount of potash has increased over that contained in older eruptions from the same vent. The lava ejected consolidates as an almost holocrystalline rock, resulting from devitrification and larger development of the microlites. The glass inclusions of the leucite are often transformed into augite and titanomagnetite. The phenocrysts of leucite developed before the lava issued from the crater, but the microlites formed during the period of superficial flow.

Nova Scotia contains many deposits of iron ore. Magnetite is present, but not in promising amounts, except as a metamorphic product from hematite. Specular hematite of high purity has been found in small discontinuous bodies. Clinton ore is present at Torbrook and elsewhere in its usual character. Limonite occurs mainly as contact deposits near the edge of the Lower Carboniferous and as an alteration product from carbonates along fissures in the Cobequid mountains. Siderite is present but unimportant. Ankerite in the Londonderry district is the immediate source of the limonite, and by exhaustion of the latter is becoming of value as a flux and as an ore. Used alone it causes irregularity in the furnace.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slime Concentration.

The Editor:

Sir—Is it to be assumed as possible to construct a slime concentrator which will prove a success with any and all slimes? The matter is one of great practical importance to mill-men. It is quite impossible for a man having to design a mill of moderate size to conduct elaborate experiments on a working scale to determine what class of machine will yield the best results. It is not everyone who has available such resources as those which enabled the Nevada Con. to erect a mere experimental plant which cost as much as most mining companies would be able to expend for their final reduction-works. A few years ago the Wilfley table was brought out as the panacea for all the ills of slime-concentration, but the vanner did not die, as was predicted, and Mr. Wilfley himself was forced to design a 'slimer' which introduced an entirely different principle from the standard type which works so successfully on fine sand. Not only did the vanner refuse to be extinguished, but it is now in the hey-day of a great revival. Is this ascendancy only temporary? Is it not possible that practice may change again? I note that the most common design of vanner has a motion quite different from the old side-shake. An oscillation, in imitation of a true vanning motion, has been introduced. On certain copper ores, and particularly those containing a great deal of clay, this type of machine gives excellent results. But is it not possible to improve on this? It is pertinent to enquire, also, why it so frequently happens that an ore crushed dry will yield better to subsequent wet-concentration than an ore crushed wet. I have found this to be the case in experiences I have had in my own operations, and I have heard others say the same. This seems to me to open up a most interesting field for study. Theoretically, either a fixed table, or a belt moving in one direction only, or one to which an oscillation was communicated, should by perfection of detail yield good concentration. For example, a plain California 'canvas floor', if kept true as to surface, and if of sufficient area, with a suitable dilution of pulp, and a proper inclination of floor, carefully ascertained by experiment for each particular ore, will yield a high efficiency. It may take an excess of water, and involve considerable labor, but I think my point can be sustained, namely, that if the 'commercial mean' be omitted from the problem, practically any type of machine may be so adapted as to yield high technical efficiency. I fancy that, in the majority of mills in America today, concentration of slime is being done along lines that approximate much more closely to a high grade of technical efficiency as regards the system used in each case, than they do to a mean of commercial efficiency such as might be attained by a series of experiments with different appliances. Now

the question in my mind is, whether the floundering that mill-men and engineers alike are compelled to do in their efforts to find a suitable machine for a particular ore, does not indicate lack of scientific study of the problem. Is it feasible to arrive at some standard type of machine for slime-concentration perfected so as to be the one always certain to yield a safe economic result, just as the stamp-mill has become the standard for crushing gold ores? The details of such a machine could then be elaborated to improve its mechanical efficiency. Is this possible? If not, are there then recognizable varieties of slimes, each of which demands some particular kind of treatment? There is no other department of ore-reduction which has lagged so far in the rear as concentration. Efficiencies in recovery of from 85 to 98% are demanded in every other branch of milling and metallurgy, but the concentrator-superintendent who can reach and maintain a recovery of 75% puts a feather in his cap. What is the solution of the problem, or why is it so long in coming?

C.

San Francisco, July 31.

Placer Mining Conditions in Colombia.

The Editor:

Sir—The successful development of the gold dredging industry in the western part of the United States and Alaska has of late years resulted in an active search for new fields offering conditions favorable for this class of mining. Numerous examinations of properties in tropical countries were made and quite a few dredges were installed on rivers in Dutch Guiana, Colombia, Brazil, the Argentine, and in other tropical or semi-tropical countries. Nearly all of these enterprises have been failures, and there has resulted among mining men a prejudice against investment in South American properties. It is the purpose of this short sketch to enquire whether this prejudice be justified.

In the first place, if a man wants to have a coat made, he goes to a tailor; if he wants his garden attended to, he seeks a gardener. If he were to have the gardener make him a suit and the tailor plant his flowers, he would expose himself to ridicule. But I know of more than a dozen cases where for the purpose of examination of gravel properties in tropical countries persons were employed who were no more fit to pass upon their merits than the gardener would have been to manufacture the coat. In one case a school-master was sent to report upon the unsatisfactory work of a gold dredge on one of the tributaries of the Cauca in Colombia, and when the pedagogue had reached the hot and sandy plains of the lower Magdalena at Barranquilla and had learned that before him lay a trip of some 300 miles into the interior, on a little steamer, with all the conveniences of travel omitted, he concluded to pass a couple of weeks at the hotel and return to his lares and penates.

In the report to his company he dwelt upon the possibilities of development and of increased production at the mine, but he took care to dispose of the stock he held in the concern. In many instances men

are selected because they have spent a number of years in the country where the property is situated, or because they have been hydraulic miners, or because they are familiar with the mechanical details of a dredge, or because they have been testing ground with a drill. These qualifications are excellent in their way, but the possession of one, or even more than one, of them does not qualify a man to judge the possibilities and value of a hydraulic or dredge mining property.

Foremost among other features which are important in the consideration of placers in the tropics is transportation. It can be stated, as a general rule, that wherever water or rail transportation to the property is available, the difficulties are not formidable.

If, however, the property can only be reached by trails over mountains, it must be a very rich one to pay for building roads over which to transport the heavy material. No one who has not traveled in tropical countries has an idea of how a heavy rain affects the trails, and how long it takes to restore them to a good condition. I append some figures, which were furnished me by C. Bimberg, of Medellín, Colombia, which are significant. The prices are for the transportation of machinery from Providencia, the terminus of the railroad, to Medellín, a distance of 65 miles, of which the first 40 miles were trail, while the last 25 were wagon-road. They represent extremes in cost.

| Kilograms. | Per carga. | Per metric ton. |
|--|------------|-----------------|
| 150, in two packages on one mule..... | \$ 6 or | \$ 40 |
| 150, in one package on two mules..... | 18 or | 120 |
| 200, carried by peones | 30 or | 400 |
| 300, carried by peones | 180 or | 600 |
| 500, carried by peones (heaviest piece) .. | 300 or | 600 |

At a time when work for the muleteers was slack, a contractor undertook the delivery of a large consignment from Providencia to the Medellín electric light plant at the following figures, and he lost heavily on the contract:

| Kilograms. | Per carga. | Per metric ton. |
|------------------|------------|-----------------|
| 150 | \$ 6.00 or | \$40.00 |
| 150 to 175 | 7.00 or | 40.00 |
| 175 to 200 | 9.00 or | 45.00 |
| 200 to 225 | 9.50 or | 42.20 |
| 225 to 250 | 10.80 or | 43.20 |
| 250 to 275 | 16.20 or | 58.80 |
| 275 to 300 | 22.50 or | 75.00 |

This latter work was done in April and May 1907, at a time when the trails and roads were in good condition, while the previous quotations were figured on a wet season's work.

Another important feature in connection with tropical mining properties is the climatic conditions. As to these, it is a safe rule to expect malarial fevers along the rivers and at low altitudes. This is especially true in Colombia, for the tributaries of the Magdalena river, such as the Cauca, Nechi, and lower Porce.

On the Pacific side, the San Juan seems to be an exception, it being free from malignant fevers. Much depends, of course, on the general health of the person and his liability to infection. While I personally have always been immune from fever in

tropical lands, others might not be so fortunate. The natives, while not severely affected by fevers in their homes, seem to be more readily attacked by them when taken to another part of the country.

Personally, I believe that a thorough sanitation of the country at and around the mining camp can be obtained, as has been done in the case of the Panama Canal zone, so that whenever the property is of sufficient magnitude to warrant the expenditure of a round sum of money for this purpose, the objections on account of climate will carry but little weight.

The importance of the climatic conditions is emphasized by the fact that for any mining enterprise in the tropics, men familiar with the handling of the machinery must be imported from the United States, as there is practically no skilled labor in the tropics.

There is a possibility for an established concern to gradually educate some of the natives so that they can fill more responsible positions, but for the present the fact remains as stated.

In Colombia, property and other rights of foreigners are religiously guarded by all parties, as long as the foreigner takes no active part in politics.

Titles to property are as a rule trustworthy and not likely to be disputed, but as land can be taken up for agricultural and for mining purposes, care has to be exercised to have both these rights, otherwise the owner of the agricultural rights might make trouble, especially if the mine is producing. I knew of one case where a mining company, after having worked out three or four acres of ground, had to pay the owner of the agricultural rights on the land about \$200 per acre. Taxes as a rule are small, as far as the ground is concerned, but an export tax is levied on the product in most of the South American republics, amounting to about 3 to 4% ad valorem.

There is no need to dwell at length on the necessity of observing minutely the physical characteristics of the deposits, as the nature of the installation will depend on them solely. I would only call attention to the importance of viewing each property as a new problem as far as installation is concerned; no fast and hard rules can be laid down. It may become necessary to work out new methods, or at least radical departures from known and approved ones. An installation at such distance from home, if not adequate in every particular, carries with it the germs of failure, and no doubt a great many of the mishaps in the tropics can be traced to the faulty installation or the premature equipping of a property.

Wherever a chance offers for the development of hydro-electric power, advantage should be taken of it, as steam generation by wood in the tropics is unsatisfactory.

So far but little is known as to the actual assay value of the deposits in the rivers and adjacent flats in the South American republics, as, with few exceptions, no attempts have been made to determine in a methodical and painstaking manner such values by drillings, shafts, or other methods.

As far as my personal observations go, and by these I mean results obtained by actual work on comparatively large areas, there are quite a number of properties which will yield from 20 to 30c. per cubic yard, and this, as far as I have been able to ascer-

tain, coincides pretty well with what has been found by others who have investigated the gravels of the Colombian rivers. I have run across properties which have yielded as high as 80c. per cubic yard, but they were of limited extent.

The economic conditions in the tropics are generally unfavorable. Labor, while cheap, is inefficient, the natives are not familiar with the use of tools, and in some localities even a shovel may be an unknown appliance. The food-stuffs obtainable are as a rule unsuited to the palate of the American, and it would become a necessity to import preserved food-stuffs from the United States or Europe, making camp expenses high. Men going into these countries are placed in surroundings entirely unfamiliar to them, the language, the customs of the country, the flora and fauna, everything is strange, and such a state of affairs is likely to produce dissatisfaction, hence frequent changes in the personnel on the property result, unless the equipment is such as to warrant the employment of a large number of Americans all the time, in which event the evil is ameliorated considerably.

It is not a poor man's mining country; it is a place where large installations must be made, and where everything must be done on a large scale. Investors in mining properties in the tropics must always keep in mind that the men at the head of the enterprise must be high-class and will require good remuneration, as they will have to cut themselves loose from their homes for a long period; and the only inducement for a high-class man to accept a position in the tropics is the fact that he receives a better salary than he would for similar work in the United States. A small enterprise cannot afford to pay such salaries. After large companies have established themselves and have shown what can be done, the smaller investments will have a chance of success, but not until then.

L. J. HOHL.

Berkeley, California, June 25.

Postal Rates on Specimens.

The Editor:

Sir—The Postmaster of El Paso, Texas, J. A. Smith, held up samples of ore addressed to the local assayers, on the ground that they should pay first-class sealed-letter rates of two cents per ounce, instead of one cent per ounce, as they had been doing for over 30 years, on the basis of fourth-class matter. The reason for this change given was that there is a line, on the outside of each mailing sack, with the printed words, "Assay for." The shipper fills in this line with the words, silver, lead, gold, or whatever metal he wishes to have determined. It is ruled that if one word is written on the outside of the envelope, although latter is unsealed, first-class sealed-letter rates must be paid. The local assayers complained that it was an undue hardship, not alone on the miners and prospectors, but the assayers also, and that this one-cent rate had been in vogue for a third of a century, in the United States as well as Mexico. Argument was useless, as the Department has decided against the one-cent rate, and from now on two cents per ounce must be paid or else samples will

be held up, unless instructions for assaying are sent by separate letter or postal card.

D. W. RECKHART.

El Paso, Texas, July 28.

[The intent of the law seems to be that any mail package carrying a message shall be charged as first-class matter. A few years ago a ruling was made at Chicago that even a word on the outside of the package indicating the nature of its contents, such as 'photographs', 'merchandise', or the like, subjected it to the payment of first-class postage. This ruling was reversed by higher officials on the ground that the message in such a case was really to the postal officials and designed to facilitate their work, rather than to the recipient. The remedy in the present case would seem to be to send tied rather than sealed bags, and to have sample bags and postal-cards numbered in duplicate. This is being done elsewhere without objection from the postal authorities.—EDITOR.]

The Wisconsin Geological and Natural History Survey, in addition to carrying on soil studies and having charge of highway investigations, both of which are supported by separate appropriations, has under way considerable geological work this season. S. Weidman is continuing his areal survey of the northern part of the State, E. A. Birge is carrying on the biological survey of the lakes and his work on the fish of the State. In addition to his work as chief of the Highway Division, W. O. Hitchkiss is preparing a new geological map of the State and getting the material together for a general elementary bulletin on the geology of Wisconsin. This bulletin will be one of the educational series, planned primarily for use in the high school and by those having no particular training in geology. The construction of a geologic and topographic model of the State is also under way. The mines in the lead and zinc district are re-opening and increasing their production on account of the stronger market for zinc. Considerable exploration for iron ore is going on in the Menomonee district, and the western extension of the Gogebic. There is some activity in exploration for copper in the Keweenawan region, in the northwestern part of the State.

Asbestos of the best quality yet found in the United States occurs near the bottom of the Grand Canyon of Arizona. It is cross-fibre chrysotile of exceptional quality. The outcrop is extensive, but as the product must be packed on donkeys about 12 miles down one side of the canyon and 4000 ft. up the other side, and thence hauled 20 miles to the railroad, only the hand-cobbed, best grade of material can be shipped at present.

Missouri's original coal supply, as estimated by M. R. Campbell, of the U. S. Geological Survey, was 40,000,000,000 short tons, included within an area of 16,700 sq. mi. The production of the State, according to the best records available, amounted at the close of 1908 to 100,935,421 short tons, representing an exhaustion of approximately 151,000,000 tons, or 0.4% of the estimated original supply.

INVESTIGATION OF FERRO-BORON.

By K. IWAI and J. C. BALLAGH.

MINING AND SCIENTIFIC PRESS prize thesis, presented to the President and Faculty of the Colorado School of Mines, June 1909.

The subject of boron in iron and steel has been investigated very little up to the present time. Practically the only investigation upon the subject was made by M. L. Guillet, at Imphy, France.* He started with an electric-furnace alloy made from iron oxide and calcium borate, prepared by Girod, containing C, 2.85%; B, 32.10; S, 0.03; P, 0.005. Two series of steels were made, one with about 0.2% carbon, the other with about 0.5. The analyses of these in percentages were:

| | C. | B | Mn | Si | S | P |
|---------|-------|-------|-------|-------|-------|-------|
| 1 | 0.180 | 0.215 | 0.076 | 0.232 | 0.012 | 0.023 |
| 2 | 0.224 | 0.462 | 0.292 | 0.163 | 0.015 | 0.015 |
| 3 | 0.207 | 0.844 | 0.600 | 0.792 | 0.014 | 0.013 |
| 4 | 0.475 | 0.155 | 0.370 | 0.283 | 0.020 | 0.020 |
| 5 | 0.281 | 1.514 | 0.600 | 0.641 | 0.005 | 0.018 |
| 6 | 0.595 | 0.406 | 0.295 | 0.293 | 0.293 | 0.023 |

Steels with higher amounts of boron than the above could not be forged.

TRANSFORMATION POINTS.—IN DEGREES C.:

| | Heating. | Cooling. |
|---------|---------------|---------------|
| 1 | 750-(830-850) | 720-800 |
| 2 | 780-875 | 750-850 |
| 3 | 780-885 | 740-(905-875) |
| 4 | 775 | 750 |
| 5 | 875-925 | 735-(800-775) |
| 6 | 785 | 760 |

The conclusions are that boron raises the transformation temperatures, excepting that the point A_3 , in cooling, passes a maximum at 0.8% boron, and descends for higher percentages.

Micrography.—After annealing the first series at 900° C., and the second series at 850°, they showed under the microscope no anomalies, except small grains of a constituent which is black with picrate of soda, and polishes white. This may be a borocarbide of iron of variable composition, according to the content of boron and carbon in the steel. When tempered, this special constituent was reduced to traces in the low-carbon series, but was still present in considerable quantities in the higher boron series.

Mechanical Tests.—The annealed specimens showed increasing strength and decreasing ductility as the boron increased, similar to increasing carbon. The tempered specimens showed remarkable increase in tensile strength and elastic limit, however, with decreasing ductility. With 0.8% boron and 0.21 carbon, the properties were:

Tensile strength, 175 kg. per square millimetre, or 250,000 lb. per square inch.

Elastic limit, 130 kg. per square millimetre, or 185,000 lb. per square inch.

Elongation, 4 per cent.

Reduction of area, 10.6 per cent.

These results are most surprising, considering the low carbon. Another unexpected property is that the resistance of this steel to shock is double that of normal steel. The higher-carbon boron-steels were practically worthless after tempering. All the low-

carbon steels after tempering worked well under the cutting tools. All things considered, 0.22 carbon with 0.5 boron, as in steel No. 2, makes the best combination for industrial purposes. It is important to remember that these steels are practically useless in the normal state or forged, but possess these remarkable mechanical properties only in the tempered condition.

Considerable time has been spent by the authors in the design and construction of a suitable furnace, capable of close regulation both as to temperature and chemical reactions involved; and owing to the limited amount of time and facilities at their disposal the only things tried after the completion of the furnace were the manufacture of ferro-boron and the microscopic examination of the products obtained. The writers wish to express their thanks to W. G. Haldane, professor in the Colorado School of Mines, for valuable assistance given by him during the experiments. New difficulties arose at each succeeding experiment; these were gradually overcome until in the last few runs of the furnace results were obtained that were very gratifying. The difficulties met were more of a mechanical nature in connection with the operation of the furnace than in the analytical or metallographic work.

For the production of ferro-boron by the direct reduction of oxygen compounds of iron and boron the indirect arc furnace was decided upon as the most easily managed and the best suited for the purpose. The body of the furnace was constructed of ordinary fire-brick. For the lining several materials were tried and rejected. Finally magnesite brick was decided upon as being by far the most refractory material available. They do, however, crack under the influence of heat, and at the high temperature used are easily attacked by the silica in the charge. The dimensions and details of construction are shown in Fig. 1. The electrodes used were made of Acheson graphite; size, 1½ in. diam.; current-carrying capacity, 1000 amperes; loss by weight, seven experiments, 230 grams; loss in length, 5 inches.

In the lining experiments the magnesite used was the commercial magnesite powder made by precipitation. This is an impalpable powder and is probably finer than 100-mesh. The experiments were as follows:

1. The magnesite was mixed with enough hematite to give a slightly pink mixture. Enough water was added to make a mixture without cohesion unless pressure were applied. Between this lining and the silica bricks on the outside was placed a thin layer of paste made by mixing powdered graphite with molasses and water. This was allowed to dry for a week, and was then slowly heated with a gasoline torch before the arc was started. Under the heat of the torch this lining crumbled, and under the heat of the arc it cracked and became a powder.

2. The magnesite was mixed with a small amount of tar, about one part tar to four parts magnesite powder. This was heated in a muffle to full red heat. The tar burned off, leaving the magnesite in the form of a powder again.

3. The magnesite was mixed with an equal vol-

*'Les Aciers au Bore', Revue de Metallurgie, Aug. 1907.

FIG. I. EXPERIMENTAL ELECTRIC FURNACE.

ume of tar. Under oxidizing conditions in the muffle the tar burned off, leaving the magnesite in the form of a powder. Under reducing conditions in the muffle the tar was converted into a coke, and left the magnesite in a porous condition.

4. The magnesite was mixed with $2\frac{1}{2}\%$ of basic slag, with a small amount of water. When heated to full red this became a powder.

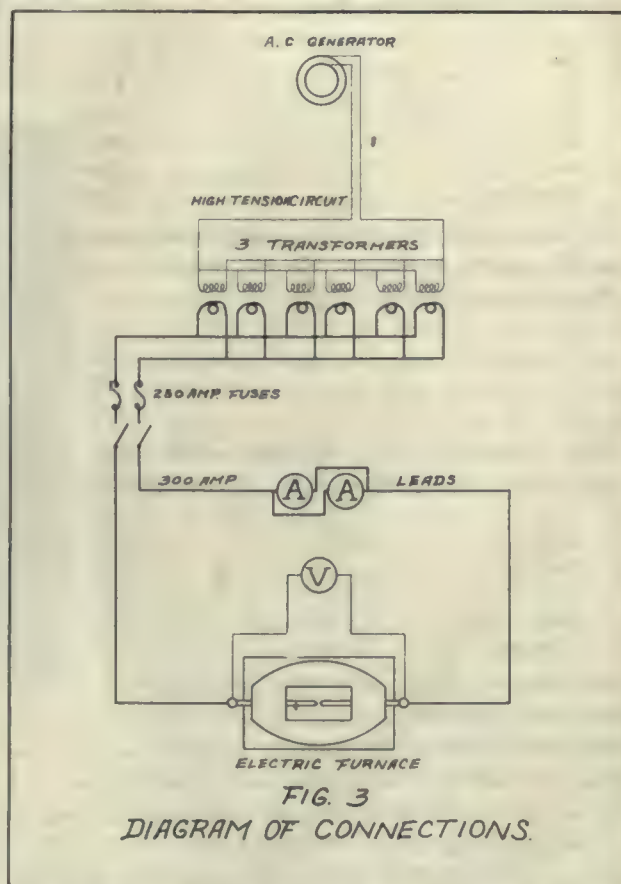

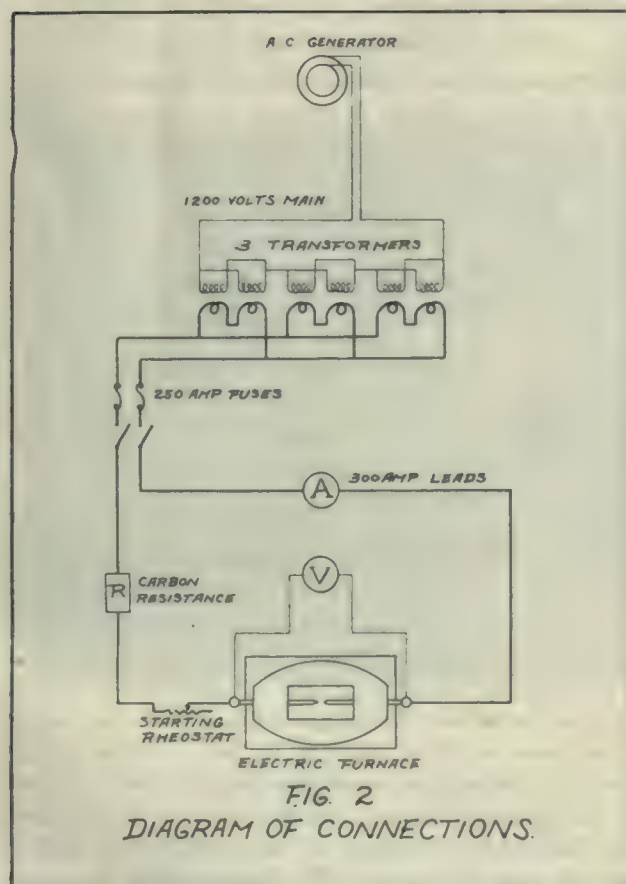

5. The magnesite was mixed with 10% of basic slag and a small amount of water. When heated to full red this became a powder, as in No. 4.

6. A fairly thick solution of water-glass (Na_2SiO_3) was mixed with an equal volume of water and two volumes of the magnesite powder. This was dried and heated to full red. A few cracks formed, but the body was firm.

furnace while hot, and, after cooling, heat was gradually applied. The carbon burned off gradually, giving a dense smoke. When the carbon had burned off, the magnesite again became a powder. Below the surface, where the air had not entered, the mass was hard.

From these nine lining experiments the conclusion seemed to be that the magnesite in itself is refractory enough, as it did not fuse in any of the trials, but a suitable binder for the precipitated variety is the main drawback to its use. Powdered magnesite will shrink to a certain extent under the influence of high heat, and this fact also renders the finding of a bond more difficult.

An experiment was then tried, using commercial magnesite brick, such as is used in the basic open-

7. A fairly thick solution of water-glass and two volumes of magnesite were mixed without water other than in the water-glass. This formed a very moist mixture. It was dried and heated to full red for a half hour. The surface was firm and without cracks, except a few minor ones at the contact of the holding vessel and the mixture.

8. Water-glass and enough of the magnesite powder were mixed to get a mass that would not cohere unless a small amount of pressure were applied. As in No. 7, this was heated to full red for a half hour. The surface was firm and without cracks. This was the lining used in Experiment No. 2 in running the furnace. It gave way under the arc and was reduced to a powder as in the previous trials. This kind of lining also proved to be of no use.

9. The magnesite was mixed with enough liquid refined coal tar (containing 5% vaseline) to make a dense pasty mass. It was rammed in place in the

hearth furnace, obtained from the Colorado Fuel & Iron Co. The outer wall was cut away, leaving enough room for one brick at the base, one at the side, two small end-pieces, and a cover of one brick, as shown in Fig. 1. The joints were made as tight as possible by rubbing, and at the contact they were rubbed with a thin paste made from the powder obtained in working the bricks to shape, mixed with a small amount of fire-clay. Between these bricks and the outer fire-clay bricks was placed a layer of the magnesite powder used in the previous experiments. This was used to keep the joints of the set tight, by ramming in between the basic lining and the outer fire-clay casing. It also would stop any metal that might leak through the cracks in the lining. These bricks were worked by hand until the desired shape of the interior of the furnace was obtained. The cubical content of the furnace was in this way reduced to 62 cubic inches.

In the electrical equipment, the generator used was a General Electric Co. A. C. of 30-kw. capacity at 1150 volts full load. The three transformers were made by the General Electric Co., with a capacity of 10 kw. each. They were connected as described under the experiment and as shown in Fig. 2 and 3. They are type H. The volt-meter used was a Cardew's hot-wire type of instrument, and was calibrated before the experiment for voltages between 30 and 40. The ammeters were made by the Westinghouse Electric Co., and each read up to 300 amperes. In the last three experiments there were two ammeters connected in parallel, so that each instrument read half of the current going through the circuit.

The iron ore used was obtained from the Colorado Fuel & Iron Co.'s Sunrise group of mines, Laramie, Wyoming. Its analysis was:

| | % |
|----------------|-------|
| Fe | 66.6 |
| P | 0.053 |
| Si | 1.928 |
| S | 0.026 |
| Mn | trace |
| Moisture | 0.045 |

The steel was the basic open-hearth variety, obtained from the Colorado Fuel & Iron Co., and was of the following composition:

| | % |
|---------|-------|
| C | 0.25 |
| S | 0.056 |
| P | 0.057 |

The colemanite was obtained from the Pacific Coast Borax Co., of New York. Its composition was:

| | % |
|--------------------------------------|-------|
| B ₂ O ₃ | 27.23 |
| CaO | 28.80 |
| H ₂ O | 25.30 |
| Fe ₂ O ₃ | trace |
| Insoluble | 0.74 |

The determination of boron, especially when combined with various metals, is very difficult, and at best is only a partly satisfactory approximation. The apparatus for the determination is as follows: A long wide-necked 200-c.c. Kjeldahl flask is used as the decomposing flask. This flask is fitted with a stopper carrying three tubes, one connected to a condenser, one connected with a flask for supplying a current of methyl alcohol vapor which is to be conducted to the bottom of the decomposing flask, this serving to keep the mixture agitated and to avoid bumping during the distillation, the third tube serving to introduce the methyl alcohol needed to form the mixture of the substance, methyl alcohol and sulphuric acid. This last tube is fitted with a clamp at the top. One to five grams of the dry finely pulverized sample is placed in the decomposing flask. A sufficient amount of sulphuric acid is added to form a thin paste, and the flask heated gently to expel carbon dioxide and volatile acids. This is then cooled. About 50 c.c. of water is placed in the receiver, the terminal tube of the condenser being made to dip into the water. The decomposing flask was then connected with the flask for the generation of methyl alcohol vapor, and with the condensers, all connected parts being made air-tight. The distillation was started by adding in one portion to the decomposing

flask sufficient cold methyl alcohol to equal in amount about twenty times the amount of free sulphuric acid present. A few cubic centimetres of hydrogen peroxide are also added. The methyl alcohol vapors are then passed from the generating flask until the boron has all gone into the receiver. This will take from 30 to 60 minutes. During the distillation the flask is heated to a temperature sufficient to prevent any marked change of the volume of the methyl alcohol which was originally added. The distillate is then neutralized with alkali, when necessary, and an amount of neutral glycerine equivalent to at least one-third the volume of the solution at the finish is added, together with about ½ c.c. phenolphthalein as an indicator. The titration is then finished with standard sodium hydroxide solution, which must be free from carbonates. The calculation is based upon the following equation:

Experiment No. 1 was the first run of the furnace, and the object was to determine the voltage across the arc, and to see how the lining would withstand the temperature of the arc. For these reasons no charge was placed in the furnace. The transformers were placed in series parallel to give a 30:1 transformation. The voltage across the arc was 20, with a current of 175 amperes. The length of the arc was not over ⅛ in. at any time. There was no permanent resistance in the circuit, but a starting resistance, made of a jar of salt-solution, was placed in series with the circuit. After the arc started this was cut out. The time of the run was 45 minutes, and at the end of that time the lining was destroyed. The effect on the lining is explained in the lining experiment, trial No. 1. A preliminary heating of the furnace was obtained by means of a gasoline torch directed through one of the electrode holes. From this experiment it was found that a suitable lining must be obtained before a run could be made.

Experiment No. 2 was performed with the same connections of the circuit as in No. 1. The lining was the water-glass lining described in trial No. 8 of the lining experiments. On the bottom of the furnace was placed a piece of steel billet, the object being to melt this steel. The furnace with the steel was pre-heated by means of the torch to dull red, and the arc was then started. After a run of one hour an attempt at tapping was made, which was a failure as far as securing any metal was concerned. After the furnace had cooled it was opened and the piece of steel was found to be partly fused. The voltage and current were the same as in experiment No. 1. From this experiment it was found: (1) That the voltage used was too low to obtain a temperature high enough to cause the steel to melt within a reasonable time. This could be altered by changing the connections at the transformers. (2) The necessity of some resistance material in the circuit to keep a steady arc. (3) The chamber of the furnace was too large for the arc used, owing to too great radiation of heat. (4) A more efficient lining should be obtained.

Experiment No. 3 represented a trial of the magnesite-brick lining, using a piece of open-hearth steel alone, the object of the experiment being to melt

this steel. Fusion was noticed to a slight extent in about 20 minutes. The metal could be seen 'teeming' through the peep-hole. The pour was made in one hour from the time the arc started. The ingot obtained was very rough, due to the too rapid cooling in the mold. The walls of the furnace were not affected to any extent by the high temperature nor by the contact with the metal. On the sides were many globules of metal that had been thrown up during the boiling of the metal.

From this experiment it was found, among other things, that: (1) There must be some regulating device by means of which the electrodes would stay the same distance apart, thus keeping a constant arc. (2) The mold should be heated before pouring, in order that the cooling should not be too sudden. (3) Careful watch should be kept to ascertain when fusion takes place. The longer the steel is in contact with the arc the greater the opportunity for the absorption of carbon by the steel. If kept in contact

to incandescence. Fusion was noted in $1\frac{1}{2}$ hours, and the pour was made 2 hours after the start. The exact time of fusion could not be determined, due to the irregularities of the arc at the start and the cooling of the charge while several burned-out fuses were being replaced. In this experiment the carbon resistance in the circuit did not become as hot as in No. 3, due to the fact that several bars of iron were imbedded in it to help its conductivity. As in No. 3, the starting resistance was not used. When complete fusion was noted by the 'teeming' surface, seen through the peep-hole, the fire-clay plug was driven out by means of a small iron rod, after the tap-hole and mold had been heated with the gasoline torch. The rod used in tapping was too small, and the stream of metal after coming part way out of the tap-hole 'froze' and blocked the further passage of the metal. It was necessary to allow the furnace to cool and partly dismantle it in order to clean out the solidified metal and charge in the tap-hole. Under

normal conditions the current was 175 amperes and the voltage across the arc was 50. The temperature was determined by means of the Wanner optical pyrometer through the peep-hole. A reading was taken before and after the attempt at tapping. In the first case the reading was taken while the arc was on, and in the second case after it was shut off. Both of these readings were 1368°C . The lining was much corroded, and where it was in contact with the charge was eaten into to a depth of nearly an inch. The bricks were covered with cracks, most of which were too small to be of any account. The brick was of a lighter color at the contact with the charge than elsewhere, and appeared to have absorbed some material to a depth of nearly $1\frac{1}{2}$ in. This was probably the slag, as there was practically none present on the metal. In this experiment the conclusions arrived at were:

(1) The tap-hole should be of ample size, and have a fairly steep angle. The gutter to the mold should not be too long. This tap-hole should be heated as high as possible before tapping is commenced. (2) As large and strong a tapping-bar as possible should be used so that a large stream of metal can flow at once after the opening has been made. (3) The carbon used should be in a form having a higher ignition-point than charcoal. Coke would naturally suggest itself. (4) A circuit-breaker of easy manipulation should be within easy reach of the operator, so that in case of a blow-out of the fuse or breaker there would be little opportunity for the furnace to cool down. (5) That too much resistance was in the circuit. (6) That the temperature was not high enough.

In experiment No. 5 both the primaries and the secondaries of the transformers were placed in parallel, as shown in Fig. 3, to produce a higher temperature. The carbon resistance used in the last experiment was cut out, and the run made without any resistance in the circuit other than that of the arc and leads. A preliminary heating of the furnace was made by means of the torch, and a run of the arc.

Furnace Used in Experiments.

with the arc too long the fused metal will boil and spatter steel on the sides, top, and electrodes. The loss of metal by air drawn in through the electrodes is greatly augmented by the increased length of time, and suitable devices should be provided for maintaining a neutral atmosphere.

Experiment No. 4 was an attempt to produce ferro-boron. The charge consisted of hematite, silica, colemanite, and charcoal, all ground to 80-mesh and thoroughly mixed. The charge was carefully calculated to produce a ferro-boron containing 50% boron, together with a monosilicate slag. It was added to the cold furnace, and the arc started without preliminary heating, the object being to avoid as far as possible the burning of the carbon of the charge. At the start the arc was unsteady, probably due to the cooling action of the walls in such close proximity. A wooden rod connected the electrode holders across the furnace and kept the electrodes at a constant distance apart. For the first 45 minutes much carbon monoxide was given off. This burned at all available cracks, and in the first part of the run showed fine particles in the flame; these were probably fine carbon particles from the charge, heated

The current was 250 amperes, and the voltage 35. The charging was done from the top, between the electrodes, and the cover put on as quickly as possible. In this run two charges were tried.

Charge No. 1; colemanite. This fusion was made in 30 minutes, and a small amount of metal obtained, but no slag.

Charge No. 2; colemanite. This fusion was also made in 30 minutes. A white powder came out with the carbon monoxide gas, probably due to the decomposition of the colemanite. From this experiment it is seen: (1) That the colemanite should be calcined. (2) That the charge should be put into the furnace in such wise as to keep the carbon from burning up before the furnace can be closed. (3) The coke burned off as quickly as the charcoal, consequently charcoal has an advantage over coke in its purity.

In experiment No. 6 the charge was fed in two portions, ten minutes apart. The total time of heating with the charge under the arc was 30 minutes. A preliminary heating of the furnace was effected by running the arc for 30 minutes. The product tapped was quite thick. Much slag accumulated, probably due to the fact that the brick lining had become saturated with slag from the previous runs. This was the most successful run so far. It demonstrated: (1) that a better heating of the tap-hole should be effected; (2) that the slag was too basic, consequently more silica was required in the charge; (3) that the charge should be coarse enough to prevent great loss; (4) that quite an excess of carbon is required in the charge.

In experiment No. 7 no preliminary heating of the furnace was tried; no resistance was used in the circuit, and the arc was constant from the beginning of the run. The voltage was 35, and the current 230 amperes. Two charges were tried, one for the formation of ferro-boron from steel and colemanite, and the other using a charge similar to that used in Experiments No. 5 and 6.

Charge No. 1. The steel block was placed in the furnace and the arc started. Fusion of the steel took place in 25 minutes, and the colemanite charge was added. After 20 minutes the charge was tapped off into a mold that had been previously heated with the gasoline torch. The tap-hole had also been to a red heat, so there was no trouble in the tapping of the product. The metal and slag obtained separated nicely.

Charge No. 2. The charge consisted of the colemanite and charcoal charge, similar to the previous experiments. There was enough used so that the metal obtained would be greater in amount than that obtained in the previous runs. The charge was added in three portions, 10 minutes apart. The total time to melt down was 40 minutes. The product obtained was greater in amount than that obtained in any of the previous runs, and was of a uniform quality. This was the best run made to date, both in regard to the operation of the furnace and in regard to the products obtained. After this run the furnace was torn down, and on the bottom was found 208 gm. of metal. This was the accumulation from the above two runs, as the furnace was clean at the

start. Therefore the loss in the above two runs cannot be told, as part of this metal may have come from each charge.

From experiment No. 7 it was determined that no preliminary heating of the furnace is required.

Details of experiment No. 7 are as follows:

| Charge No. 1. | Grams. |
|--|--------|
| Steel | 1,130 |
| Colemanite | 130 |
| Silica | 20 |
| Voltage | 35 |
| Amperes | 230 |
| Time (total), minutes | 45 |
| Metal obtained, grams..... | 892 |
| | % |
| C | 1.13 |
| B | 0.28 |

Microstructure of the metal is shown in Fig. 4.

The metallography of the products is as follows: the metals obtained from experiments No. 5, 6, and 7 were very brittle, and were hard enough to cut glass. They had a conchoidal white fracture, and a close-grained structure. No peculiarity of structure was noticed under the microscope, but the presence of a solid solution of iron-boron-carbon was observed as shown in Fig. 4, 'A'. After re-heating and quenching at a temperature of 800-900° C. the round grains disappeared as shown in Fig. 4, 'B'. The brittleness also disappeared. This accords with the result of investigations made by M. Guillet.

All of the sections were etched after polishing with a 5% ethyl alcoholic solution of picric acid.

Fig. 4 'A'. Metal from experiment No. 6, charge No. 1. The dark parts are pearlite, and the ground-mass is cementite. The round grains are presumably solid solution of iron-boron-carbon.

Fig. 4 'B'. This is the same section quenched at 800-900° C., and under the glass shows the rounded grains to have disappeared. The hardness and brittleness were also eliminated as indicated above.

Fig. 4 'C'. Metal from charge No. 1, experiment No. 7. The dark part is pearlite, and the white part is cementite. No indication of a solid solution as in Fig. 4 'A'.

Fig. 4 'D'. Metal from charge No. 2, experiment

Fig. 4. Microstructure of the Metal.

No. 7. The dark part is pearlite, and the light part is cementite. No solid solution was visible, and the ratio of pearlite to cementite checks closely the chemical results for carbon, hence the conclusion that the boron in this instance is contained in the eutectic of probably ternary type.

Fig. 4 'E'. Metal from charge No. 1, experiment No. 5. This section showed many blow-holes which interfered with the examination to such an extent that the constituents could not be identified.

Conclusion.

1. According to the experiments performed, ferro-boron can be made in the arc-furnace by the direct reduction of iron ore and colemanite with a limita-

tion of 1% boron in the metal, using the temperature and charges available in these experiments.

2. Charge No. 1 of experiment No. 7 proves that, at high temperature, colemanite, when heated in contact with molten steel, gives up some of its boron to the steel, forming a ferro-boron.

3. The avoidance of a loss of boron in the slag is an important factor in the production of a high ferro-boron.

4. From the analysis of the slag it is seen that at a high temperature magnesium oxide has a higher affinity for silica than either calcium oxide or ferrous oxide. This means that magnesite is not good as a permanent lining for this operation unless the charge is changed.

5. If anhydrous borates are used it would seem that a higher boron-content would be obtained.

6. No special resistance is required in an alternating current circuit to obtain a steady arc unless the resistance of the circuit is very small. There seems to be no difference in the operation, whether the furnace is pre-heated or not.

7. Closer regulation of the carbon content would give more satisfactory results for metallographic investigation.

The Grant's Pass region of Oregon has recently been studied by J. S. Diller and G. F. Kay of the U. S. Geological Survey. The region covers about a thousand square miles, and has produced considerable amounts of gold and copper, the total mineral production in 1907 being valued at nearly half a million dollars. It is mountainous, and ranges in altitude from about 871 to over 7043 ft. above the sea. The fertile valleys are farmed and the mountains are generally well forested, especially in the southeastern portion, which belongs to the Siskiyou National Forest. The region is reached by a stage mail route, which follows Applegate river to the crest of the Siskiyou mountains in California. The most productive gold-quartz claims in operation during the summer of 1908 were the Braden and the Opp. The Granite Hill and Mountain Lion mines, although not now being worked, have also been fairly important producers within the last few years. There are many mines and prospects on which work is not now being done, some of which have never produced, some of which have produced ore worth a few hundred dollars, and a few which have yielded as much as several thousand dollars. Some development is in progress on new prospects and on mines which were until recently closed. The total production of the gold-quartz mines in 1907 was about \$70,000.

West Virginia's total production of coal to the close of 1908 amounted to 476,096,382 short tons, equivalent to an exhaustion of 715,000,000 short tons, according to E. W. Parker. Estimates by I. C. White, State Geologist, and M. R. Campbell, of the U. S. Geological Survey, based on recent study of the coal-fields, place the original supply in West Virginia at 150,000,000,000 short tons. The apparent supply now available therefor amounts to 149,285,000,000 short tons, about 3500 times the production of 1908 and 2400 times the exhaustion represented by that production.

SMELTER VERSUS OIL FUME.

Written for the MINING AND SCIENTIFIC PRESS
By EUGENE B. BRADEN.

The general public, which has only a hazy notion about mining and smelting matters, outside of the stock market, seems to feel that smelting plants are a common nuisance. As to their benefit and absolute necessity to the great mining industries of the country, the public seems to have little knowledge, and to care less. There should be a better understanding of the subject, since the interests involved are so great, not only in annual monetary output, but in the matter of the large investments at thousands of mines, and in the number of men employed in the various fields. The closing of any large custom smelter would result also in closing a great number of widely scattered mines. Therefore the operation of a smelting plant is not a mere local question. It is not every mining company which can afford to erect a reduction plant to handle its own ores, and even those which have mills for crushing ore must finally have their concentrate worked at the smelter. The sulphide concentrate is always of more value per ton than the ore which is milled.

In California last year the quartz mines yielded and milled 1,654,000 tons of gold ores, which yielded an average of \$5.71 per ton in gold and silver at the mills on the plates. From this ore was saved by concentration 32,000 tons of sulphides, which was sent to the smelter and yielded over \$50 per ton, thus adding to the original value of the ore, but which had to be smelted to be utilized. In addition, there were 375,000 tons of ore smelted in the State. In Nevada, in the same period, there were 436,000 tons of ore milled, yielding an average of \$9.58 per ton, but the concentrate saved and smelted was worth \$63 per ton. In addition, Nevada had 200,000 tons of ore which had to be smelted, and which yielded \$57 per ton. In these two States, therefore, California and Nevada, if smelters had not handled the concentrate and smelting ores, the miners would have made a mighty poor showing for their work. It will be noted that the concentrate and the smelting ore were the most valuable products of the mines, yet the mills alone could not treat these.

It may thus be seen that to mine for gold and silver profitably there must be smelters to handle certain portions of the product. Copper and lead ores must all be smelted to get the metal. Moreover, when either placer or quartz gold miners get out their gold, it must be refined, and this is mainly done by the smelting companies which have refineries in their plants. When a miner sends his gold down he can get the cash for it in two days, before the refined gold is sent to the mint to be coined. The smelting plants in Shasta county, which handle copper ores and turn out from 6 to 7 million dollars' worth of metal yearly, are owned by companies which have mines of their own. Some gold and silver ore is bought from quartz miners, however, to mix as flux with the copper ores. The only large custom smelting plant in the State of California is that of the Selby Smelting & Lead Co., of San Francisco, with smelting works near Vallejo Junction, on Carquinez Straits, at the head of San

Pablo bay. By a custom plant is meant one which works ores or bullion sent to it by anyone for a specified charge. This plant handles large quantities of material, not only from the Pacific Coast States, but from Canada, British Columbia, Mexico, the Central American States, and South America. Eventually all the Klondike and Alaska gold comes to this city, and a certain proportion is handled by this company. Base lead bullion is also sent for refining from Washington, British Columbia, etc. Last years these works handled an amount equal to one quarter of all the gold produced in the United States, or upward of \$25,000,000. Its output of gold, silver, and lead that year was over \$35,000,000. This year there is a marked increase. It may surprise many to learn that last Month, June 1909, the Selby company turned out \$4,000,000 in gold, 1,500,000 oz. silver, 5,400,000 lb. of pig-lead, 500,000 lb. of white lead, 200,000 lb. of sheet-lead, 225,000 lb. of shot, 300,000 lb. of copper sulphate, and 3,000,000 shotgun shells, besides several minor by-products. The great industrial importance of this plant is thus manifest. About 500 men are directly employed, with a payroll of over \$500,000 per annum, and indirectly about 3000 persons are dependent on the operation of this extensive plant. The Selby plant is really a clearing-house in California for the precious metals produced in this State and the surrounding ones, as well as the foreign countries on the Pacific Coast.

Notwithstanding the vast interests involved, if twenty or thirty farmers in Solano county and the citizens of the small town of Benicia are listened to, this institution may be closed indefinitely. The cities of Los Angeles, San Diego, and Seattle have for years been trying to get a similar plant established near them for the mining business it brings, because those cities would thus become mining centres. They have offered large bonuses to bring this about. In fact, had it not been for the Klondike and Alaska mines, and the resultant gold and trade it brought, Seattle might have continued to be a small place, instead of trying to rival San Francisco as a great Pacific port. While the Selby plant is about 30 miles from San Francisco, the main offices of the company are in the city, where the business is handled, the gold and silver coming to the local mint for coinage, and the manufactured products being sold here. Thus it is decidedly a San Franciscan institution.

The cause of complaint against the smelting company on the part of the Solano county farmers and the citizens of Benicia is the smoke coming from the stacks of the plant on the Contra Costa county shore. They have succeeded in obtaining an injunction limiting the working of the plant in certain months each year, and within a month the matter comes before the courts for final action. The company has expended over \$100,000 in improvements to prevent possible damage from fume, and has entirely eliminated the elements originally complained of. Its contention now is that the unpleasant odors experienced at Benicia do not arise at the smelting plant, but come from the refining of crude California oils and the manufacture of asphalt from these oils, by other concerns.

The history of the present litigation, in brief, is

that in 1905 certain Solano county farmers brought suit for loss of horses killed by feeding on plants on which fume from the smelter had settled. These suits were brought prior to the time the present owners of the Selby plant took it over, and were satisfactorily settled. When the present company took hold, it started to build a 'bag-house', but work was delayed by the disaster of 1906, and the cotton bags first used did not satisfactorily arrest the escaping lead fume. Finally woolen bags were substituted, which are perfectly satisfactory and serve the purpose. Prior to the erecting of the bag-house, early in 1908, certain lead particles were undoubtedly emitted into the atmosphere, but the particles of lead are now mechanically precipitated into compartments below, together with the carbon resulting from the use of coke in the blast-furnaces. There is absolutely nothing now escaping into the surrounding country which could prove a detriment to animal or vegetable life.

But there was still another source of annoyance. The Selby company refines its 'dore' metal (gold and silver bullion) by what is known as the sulphuric acid process. The gold and silver are placed in large iron pots with sulphuric acid, and on heating, the silver goes into solution with the sulphuric acid, and the gold is precipitated, gathered up, and made into fine bars. The silver is subsequently precipitated by using copper plates. In this boiling process a dense fume of sulphuric acid is thrown into the air, and it will be remembered by passengers on the Southern Pacific road when passing through Vallejo Junction, that the effect of this fume was felt. These are of the same character as those formerly given off from the U. S. Mint in San Francisco. The apparatus invented by F. G. Cottrell, of the University of California, has for the past year entirely eliminated this feature of the alleged nuisance. This electrical contrivance precipitates the sulphuric acid fume within the works, and nothing now escapes, whereas formerly dense clouds were emitted into the atmosphere.

Coming now to the stack from which the roaster fume is emitted, it is claimed by the Selby company that the fume will not and does not damage the surrounding country. The fume comes from the furnaces in which are roasted the sulphide concentrate from the gold-mills along the Mother Lode and other parts of this and neighboring States. The concentrate contains sulphur, and in order to put it into condition to be smelted in blast-furnaces and to recover the gold and silver, it is necessary to drive off this sulphur by roasting. The type of roaster used is the Ropp, and is continuous, that is, the ore is continuously fed into it, and is turned over and over by moving plows or rabblers, so that the heat can reach all portions and set the sulphur free. This done, the material is otherwise treated. The particular type of roaster in use at this plant admits large quantities of free air, so that the sulphur fume emitted from the stack is in a more dilute condition than the fume coming from any other roasting operation in this country. Various experts have made exhaustive tests, so it is believed that no damage can result.

Careful investigation in the neighborhood of the plant from 100 yards to five miles distant, reveals absolutely no damage to shrubbery or to growing crops. In the injunction issued by the local court in Solano county, at the instance of the people of Benicia, no claim of injury to crops was made. The plea was that the fume was a nuisance, nauseating, and generally objectionable. In the latter part of May, 1908, it was arranged with certain Benicia citizens, in order to determine if the Selby plant was the cause of their trouble, to close the plant. This was done, and even the fuel oil used at the boilers was shut off, so there was not one atom of smoke of any kind escaping from the stacks on May 30. The next morning, however, there was great complaint at Benicia, and statements were taken from 27 prominent citizens to the effect that the smelter must be running, as they smelt the fume. They were invited to visit the plant to see that it was really closed. Again on July 28 nauseating fume was detected at Benicia, but the citizens who came to the smelter found that the roasting furnaces had been closed for four days. Some who visited the plant found the noxious odor coming from the windward of the smelter. Considering the affidavits submitted by the residents of Solano county, the fume which had been troubling them was again noticed in the latter part of August, but during this period the roasters of the Selby plant were not in operation, and nothing but the smoke from burning oil was escaping from the roaster stack. The Selby plant was again closed during the latter part of May, this year, yet complaints were regularly made by people experiencing discomfort from fume supposed to come from the Selby works, though no fume was emitted, the roasters not being in operation.

Tests made by experts on the gases escaping when asphalt is being manufactured from crude petroleum show that these gases are at least 4000 times as strong as sulphuric acid gases. That is, given a definite quantity of sulphurous acid gases, in a closed room, the experts are able to detect, by the sense of smell, one part in 150,000. Given a definite quantity of gases coming from the distillation of crude oil in making asphaltum, the experts are able to detect, by the sense of smell, one part in 60,000,000. It has therefore been demonstrated that the gases made in distilling crude oil are 4000 times stronger than those from burning sulphur ores. It is also calculated that 30 lb. of these gases given out in the distillation of oil will be perceptible in a volume of air 2000 by 500 ft. and 5 miles long, equivalent to the burning of 25 tons of ordinary concentrate; but it must be remembered that this sulphur must be evolved in a single instant to produce the same effect as the 30 lb. of gases given out from the oil, which is an utterly impracticable thing to do.

During many hours out of each 24 no complaint is made by citizens of Benicia; it is usually made during the early hours of the morning, although the velocity and direction of the wind has not changed. No complaint is made at other periods of the day, either at noon, at 3, at 6, or at 10 p. m. Yet the Selby roasters during all that time are emitting the fume of sulphurous acid in a diluted state. If the fault

lay with the Selby plant there should be continuous cause of complaint while the wind blows in that direction. It is, therefore, justly contended that the source of the trouble should be sought elsewhere. The atmosphere on the beach at the Pacific Ocean is free from sulphurous acid, but tests made in San Francisco, Oakland, and Berkeley show that the amount of sulphurous acid in the air is constantly increasing. Immediately to windward of the Selby plant, during the prevailing winds of the summer months, the atmosphere shows practically the same quantity of sulphurous acid gases as at the city of Benicia, $5\frac{1}{2}$ miles distant, which is to leeward of the Selby plant. In any community where sulphur is burned the atmosphere becomes contaminated. In the city of New York it has been shown that fully 1300 tons of sulphurous acid gas are evolved into the atmosphere daily by the burning of anthracite and bituminous coal.

All of the crude oil of Californian origin which is consumed in San Francisco, Oakland, Berkeley, and the industrial communities along the bay shore, contains certain percentages of sulphur, and a large portion of this sulphur is emitted into the atmosphere daily. Under certain conditions it is true that sulphurous gases put into the atmosphere will do damage, but these conditions do not prevail at or near the Selby works. The large fields of California poppies in bloom at certain seasons along the shores of Carquinez Straits are in no way damaged by the fume which in a dilute condition beats down upon them. The Omaha smelting plant, belonging to the allied interests of the Selby company, has been operated within a mile of the post office in Omaha for the past 25 years, and there has been no complaint. This is as like the Selby plant in its operations as any smelting plant known. No copper ores are handled at the Selby plant. In that connection it should also be recalled that Judge Hunt has found, in the famous Anaconda (Montana) case, that the sulphurous fume emitted from the stacks of the Anaconda company has done no damage to vegetation or live stock. As a result of tests it has become evident that oil products are immeasurably more effective on the olfactories than is sulphurous acid gas. The 'rotten egg', garlic, onion, and similar smells complained of by citizens of Benicia are not from fume produced by the smelter, but are from the vapors and gases emitted from the oil refineries. The Selby company has no desire or intent to damage or inconvenience its neighbors in any manner, and it has taken such steps to ameliorate the old conditions that they are now practically non-existent.

Dredging ground in South Africa has recently been investigated by P. W. Tewksbury, managing director of the South African Gold Dredging Syndicate, who reports that J. C. Watson, formerly Prime Minister of Australia, their representative, has completed negotiations for the option of a large area of country reported to be very rich. The vendors claim that the property is worth several pennyweight per yard, but with the Victorian methods of dredging, a few grains per yard will be considered a handsome proposition. Mr. Watson is now actively engaged in

prospecting and proving the value of the ground, so that he will be in a position shortly to advise the syndicate as to its actual gold value.—*Australian Mining Standard*.

CONSERVATION OF NATURAL RESOURCES.

The report of the National Conservation Commission of 1908 finds an echo in a bulletin (No. 394) just issued by the U. S. Geological Survey, in which are re-printed the papers on mineral resources contributed to the conservation report by members of that Survey.

Coal is considered first, and it is shown that waste in mining loses forever about one-half as much as is marketed. This half is either left in the ground in thin beds or in the shape of pillars to support the roof. Coal has been extensively mined in the United States for not much more than half a century, but the consumption is increasing so enormously that if this increase should continue all the easily accessible coal would be exhausted by the year 2040. It will, of course, not continue at such a rate, for the increasing scarcity will raise prices and check consumption. Water-power, too, will undoubtedly largely take its place. With regard to petroleum the situation is a good deal more serious. Petroleum has been used for less than 50 years, and it is estimated that the supply will last only about 25 or 30 years longer. If production is curtailed and waste stopped it may last till the end of the century. The most important effects of its disappearance will be in the lack of lubricants and in the loss of illuminants. Animal and vegetable oils will not begin to supply its place. This being the case, the reckless exploitation of oilfields and the consumption of oil for fuel should be checked. In natural gas the waste is enormous; 1,000,000,000 cu. ft. are estimated to be wasted into the air every 24 hours. The gas supply will last about 25 years—about as long as it has already been utilized.

Iron is very abundant in nature, but usually is found in ores so poor that it cannot be extracted at any reasonable cost. The best ores are being rapidly worked, and it is estimated that within 30 years they will have been exhausted and that it will be necessary to resort to ores that cannot now be worked at a profit. This, of course, means higher prices unless new and much cheaper processes shall have been invented. Gold, silver, and zinc are all so abundant that the supply is likely to last for centuries. Copper is also abundant, but is largely in low-grade ores which cannot now be profitably worked. At increased prices, however, the supply will probably be abundant. For lead, however, the outlook is much less favorable. Its production in the United States is still increasing slightly, but is decreasing elsewhere in the world, and this despite a marked increase in prices. Probably the world's output has already reached a maximum and will henceforth decline. The phosphates, it is estimated, will be exhausted in about 25 years, and the farmer will then have to look elsewhere for fertilizers.

Fresh supplies of all materials may, of course, be found, but (except for gold) it seems unlikely that they will be great enough or valuable enough to materially affect the estimates.

A RUSSIAN MONEY TRUST.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE E. WALSH.

Without exactly understanding the American meaning of a 'trust', a small coterie of mine owners, backed by the Russian Government, has enjoyed for years one of the closest monopolies of the world, and although the United States Government, through its Geological Survey, has been working overtime to break up this foreign 'trust', very little actual headway has been made. The singular workings of this trust may easily be accepted as an example of the uncertainties of any attempt to corner the market on an article needed the world over, and the peculiar desperate attempt made to relieve the strain at a time when the article became a drug on the market finally resulted in what might be called a money-trust.

Until quite recently the Russian Urals supplied 95% of the world's platinum. For upward of a century the production of this metal in other countries was almost a negligible factor. Half a dozen mine owners control the platinum-producing districts of the Urals around the mining settlement of Miac, but the Russian Government keeps a close watch on the mine owners, and knows to the very ounce how much of the precious metal is taken out. Many times in the past Russia has used this absolute monopoly to pay her debts, and after the close of her war with Japan she increased the price of platinum to help her recuperate.

But the story of the platinum trust in Russia dates back to an early period. Early in the present century the control of the platinum output was so rigorously enforced by Russia that the price was forced too high for the demand, and it became a drug on the market. The price dropped, and still the supply was ahead of the demand. Finally in desperation the Government sought to relieve the strain by adopting a course which the free-silver advocates worked so hard to accomplish in this country, namely, to advance the price to accommodate the mine owners. Platinum was adopted as a metal for money, and from 1828 to 1845 the three, six, and twelve-rouble coins of Russian money were made of platinum. The St. Petersburg national mint issued many millions of dollars' worth of money of fine platinum. This government edict saved the platinum trust from bankruptcy, and the mine owners as well as the Government profited for a season by the move. But platinum proved an uncertain and unwieldy metal for money purposes, and in time the Government had to drop it. Platinum is so hard that it is difficult to work, and the Government found, to its cost, that it could not mint and then re-melt and coin it again except at an enormous expense. The following is the official reason given for dropping platinum and returning to gold as a standard money metal:

"The essential quality of a monetary metal is its power to pass almost without expense from the form of the ingot to that of money, and vice versa. An ingot of gold duly refined can be moneyed, and the money thus obtained be re-cast in ingot, without the total expense of this double operation (coining and

re-melting) exceeding one-half per cent of the value of the fine metal."

But platinum, owing to the difficulty of re-melting and coining, cost as much or more than the original metal mined, and the Government found that its method of relieving the miners worked around in a circle. It was providing the metal a market, but it could not re-use it again for coinage except at a loss when it was worn down to a point where it was below weight or the figures on it were undecipherable. The coinage was then changed to gold again, and the platinum money recalled and exchanged.

Then one of the curious phases of Russia's national life was revealed. It was found impossible to bring out from its hoarding place the platinum money. The official publications announced the change in the metal for money, but not much more than half of the old platinum money was ever offered for redemption. The Russian mujiks living in the remote villages are great hoarders of money, and distrustful of everybody and everything. They either never heard of the change in the coinage, or, taking it as a ruse of the Government to get hold of their wealth, they refused to part with their platinum. Meanwhile, the demand for platinum in the arts and sciences increased rapidly, and its price advanced accordingly. It reached a par with gold and then passed it. When its value surpassed that of gold some energetic efforts were made to get hold of the old hoarded platinum money, but even when the metal was at twice the value of gold, very little came from its hiding place. Some enterprising speculators sought to entice the platinum from the mujiks by going from one remote village to another, offering a good premium for the old coins. But official corruption and robbery had made the mujiks suspicious, and they calmly declared they had no platinum money. The speculators tried every art and device, and finally had to abandon their quest.

It is more than half a century now since the platinum money was officially withdrawn from circulation, but over half a million dollars' worth of the coins is hidden away, and only occasionally small quantities leak out and find their way to the Government mint. Naturally the finder of this platinum money takes it readily in exchange for gold, and then reaps a big premium in selling it in the open market. Russia's monopoly of platinum has held without serious drawbacks for upward of a century, although the United States has made strong efforts to break the trust. The experts of the Geological Survey have been steadily hunting the different parts of this country for platinum deposits, and with some fair success in recent years. Platinum was found in the Republic of Colombia as far back as 1735, but it was considered worthless and thrown back into the tailing piles. Since then small quantities of it have been discovered in South and North America. The experts have expected to find deposits of the metal in Alaska, but no great discovery has yet rewarded them. Gold and platinum occur together in the Ural mountains, and there is apparently no reason why the 'white gold' should not be discovered in mines in this country. Thirty or forty years ago platinum was worth about two dollars an ounce, but today it

ranks alongside of gold. Nearly every country of the world has had experts hunting platinum deposits, and claims have been made frequently that it had been found; but it was in such small quantities that it has not seriously affected the price.

Only two metals have a higher specific gravity than platinum—osmium and iridium. Until the electric furnace was invented osmium had never been melted. Even the melting point of platinum is 1779°, and that of iridium a little higher. The famous metric bar preserved at Paris, which serves as an international measure, is made of platinum with 10% iridium.

Platinum has been mined ever since the ancient Egyptians used it for various purposes, but all of that metal ever discovered and mined from that early date up to the present would hardly exceed 100 tons. The largest nugget found weighed about 20 lb. The total annual product of the platinum deposits of the Ural mountains does not exceed in value \$2,000,000.

For these and similar reasons Russia's exclusive monopoly has a pretty firm grip, and there is no way to break it without a new discovery of an unusual supply. The gold miner hunting for his elusive precious yellow metal might well keep a sharp lookout for the 'white gold'. A single deposit, one-tenth the size of many gold mines, would enrich one enormously and prove of world-wide importance.

Coal is found at many points in Alaska, but detailed estimates of coal reserves cannot as yet be made. Even where a coal field has been both developed and surveyed in detail, there is a very large amount of uncertainty in all tonnage estimates. Moreover, according to the U. S. Geological Survey, the Bering and Matanuska fields, which contain the most valuable coals of the Territory, are regions of great structural complexity, which introduces another factor of error. In Alaska only between 300 and 400 square miles of coal-bearing rocks have been surveyed in detail, and the data in regard to the remaining 800 square miles believed to be underlaid by coal are very meagre. It is estimated that the unsurveyed coal fields cover 12,000 square miles, but of these fields only the general outline is known, and they must be surveyed to ascertain how much of the area is underlaid by workable coal-beds. It should be remembered, also, that more than a third of Alaska is almost unexplored. The facts clearly show that the present low status of coal mining in Alaska is no criterion of the future importance of this industry. Up to the present time coal has been mined only for local markets, and the high-grade fuels of the Bering river and Matanuska fields are practically untouched. These two fields can ship coal only when railway connection with tide-water has been established. Some progress was made on such railways during 1908, but it will probably be two years before any considerable shipments are made. In both these fields the activities in 1908 were largely confined to surveys for patents, assessment work, and trail and road building. Up to the close of 1908 no patents for coal lands had been issued, and this tended to discourage development.

MINERAL PRODUCTION OF VIRGINIA IN 1908.

Written for the MINING AND SCIENTIFIC PRESS
By T. L. WATSON.

The statistics of production and value of the mineral resources of Virginia for 1908, collected by the Virginia Geological Survey in co-operation with the Division of Mineral Resources of the U. S. Geological Survey, are given below in tabular form. The figures are well below the totals of most of the materials recorded for 1907, and clearly indicate the effect of the recent business depression arising from the monetary troubles. The setback will undoubtedly prove, however, only temporary, as already there has been a considerable revival in mining interests throughout the State. The decrease in production and value of the mineral resources in 1908 over that of 1907 is especially noticeable in the larger industries, such as coal and coke, clay products, iron ores, stone, talc, and soapstone. Some of the smaller ones, indeed, show a marked increase. The total value for the year 1908, exclusive of gold and silver, lead, zinc, and copper, is \$12,049,717, or about 70% of the production for 1907.

PRODUCTION AND VALUE OF MINERAL RESOURCES
IN VIRGINIA IN 1908.

| | Quantity. | Value. |
|--|------------|--------------|
| Coal, short tons | 4,259,042 | \$3,868,524 |
| Coke, short tons | 1,162,051 | 2,121,980 |
| Clay (brick and tile), thousands..... | 205,235 | 1,499,130 |
| Iron ores, long tons | 692,223 | 1,465,691 |
| Lime and cement, barrels..... | 1,629,178 | 775,660 |
| Talc and soapstone, short tons..... | 19,616 | 458,252 |
| Pyrite, long tons | 116,340 | 435,522 |
| Granite | | 321,530 |
| Limestone | | 280,542 |
| Mineral water, gallons | 2,009,614* | 207,115 |
| Slate, squares | 41,678 | 194,356 |
| Sand and gravel | | 119,095 |
| Manganese and manganiferous iron ore, long tons | 6,418 | 63,324 |
| Pottery | | 37,777 |
| Sand-lime brick, thousands | 6,181 | 36,934 |
| Millstones and sandstone | | 10,554 |
| Mica, short tons..... | 442 | 7,346 |
| Sheet, pounds | 13,427 | |
| Scrap, tons | 46 | |
| Clay mined and sold..... | | 3,250 |
| Miscellaneous (mineral paint, barytes, gypsum, feldspar, salt), short tons | 25,499† | 143,135 |
| Total value | | \$12,049,717 |

*Exclusive of 119,672 gal. used for soft drinks.
†Exclusive of salt.

In addition to the above, Virginia produced in 1908, 25,087 lb. of copper, as against 57,008 lb. in 1907; 910 short tons of spelter; and 13 of lead as against 82 in 1907. The returns for gold and silver production in Virginia for 1908 are not yet completed, but they will probably be less than for the preceding year (1907), in which year they amounted to only \$8400 in value, \$100 of which was credited to silver. There was no production of arsenic, asbestos, fluorspar, graphite, quartz, nickel, phosphate, and rutile in Virginia in 1908, although preparations are being made for the resumption of mining of a majority of these in 1909. A product of which Virginia has a practical monopoly in this country is rutile. It occurs in Nelson county in extensive deposits of superior quality, in two distinct types.

BROWN TYPE OF LABORATORY AGITATOR.

Written for the MINING AND SCIENTIFIC PRESS
By T. S. LAWLOR.

The need of an efficient scheme of air-agitation in laboratory tests to parallel working conditions in cyanide treatment where agitators of the Brown or Pachuea type are to be used, led to the adoption of the apparatus described below. The photograph shows a battery of five agitators that was used for a number of tests, with satisfactory results.

Agitators No. 1 and 2 were working at the time the photograph was taken. No. 3 is empty and shows the method of introducing the air-pipe through the inverted cone of rubber cork in the neck of the bottle, forming the bottom of the agitator. No. 4 shows a settled charge of 25% solids (200 gm. of ore and 600 c.c. of solution). No. 5 is being used as a percolator, the heavy sand forming a filtering medium.

In the section the position of the cork, the central column, and the air-inlet are shown in the positions found best suited for continuous agitation. A is an ordinary brandy bottle, chosen on account of the

Battery of 'Brown' Agitators.

slope at the neck and of its capacity. B is a 3/4-in. gauge glass tube, 8 in. long, the centre of which is directly over the air-inlet. This size of tubing measures about 7/16 in., inside diameter, and is accordingly rather out of proportion, but was preferred on account of the tendency of the bubbles of air to get outside a smaller column when re-starting agitation after settlement. C is a No. 3 rubber cork, first bored for 1/4-in. glass tubing, then cut from the extreme upper edge toward the centre to form a conical bottom below the central column. This cork should be firmly set into the neck. D is 1/4-in. glass tubing, with the end closed to about 1/64 in. by heating without drawing out. The closed end is so inserted that it just enters the bottom of the cone. EE are iron wire supports, bent as shown, to hold the column firmly.

The height of the central column above the air-inlet can be determined by test, using the smallest possible amount of air to agitate, and care should be taken to have the centre of this central column directly above the air-inlet, and also to have it centrally

disposed in the bottle. Glass tubing is more suitable for the central column than iron pipe, on account of having a smoother surface, which provides for being more easily cleared of packed sand or slime if for any reason agitation be stopped.

A mere puff of air is required to maintain agitation in these bottles, but by using well ground pet-cocks the battery shown was operated continuously with air taken direct from a receiver registering 100 lb. pressure, no reducing valve being necessary. Where compressed air is not to be had, a portable blacksmith forge or electric fan can be arranged to run continuously, and give all the air necessary. In

'Brown' Type Air Agitator. Section Through Centre.

starting a test with pulp containing 25% solid, 600 c.c. of solution is placed in the bottle and the pet-cock opened just enough to start circulation; 200 gm. of the ore is added slowly, so as not to stop agitation; when charged, the upward flow in the column is reduced to the minimum by shutting off the air until the solids at cone are just kept from packing. After agitation is finished, the clear KCy solution is withdrawn, and wash water added to bring the pulp to the original level. Lift the column and clear it from packed solids by moving gently up and down in the solution. While holding the column a little above the regular position, turn on light air-pressure and gradually lower until agitation starts again.

A series of KCy tests were run on slime all of which passed 200 mesh, as well as on an ore containing 5% of heavy sulphides and giving the following screen analysis:

| | % |
|------------------------------|------|
| Between 40 and 80-mesh | 26.7 |
| On 150-mesh | 22.3 |
| Passed 150-mesh | 51.0 |

Perfect agitation was obtained with pulp containing 25% solids.

The agitator will work equally well on slime, sand and slime, heavy sand, or concentrate, and even concentrate in a pulp containing 40% solid matter can be agitated if desired.

After washing, the tailing can be readily removed without addition of excess of water for rinsing. The charge is allowed to settle, and the supernatant liquor is siphoned off until within $\frac{3}{4}$ in. of the top of the settled solids. The bottle is then taken from stand, the air-inlet pipe is withdrawn from below, leaving the hole in the cork, through which, with a little shaking and whirling of the pulp, the entire charge may be run out upon a filter. When the ore contains a sufficiently high percentage of coarse material, as in the screen analysis given above, the bottle with the column removed may be used as a percolator. The sand forms a filter above the small opening in the air-inlet, and a few taps upon this will be found sufficient to start the percolation of clear solution after perhaps a little of the finer material has filtered through, which may be released on top.

MINERAL DEPOSITS OF TREBIZOND.

The district of Trebizond, which embraces the northeast quarter of Asia Minor, has been only superficially explored, although there are many places where the Greeks and Romans extracted ore. Their methods were primitive. They left around their diggings quantities of ore which with modern methods of extraction would be considered worth working. Copper, iron, manganese, gold, silver, mercury, zinc, antimony, arsenic, coal, and petroleum are known to exist. Under favorable governmental conditions this country will offer great inducements for mining enterprises. A new mining law, modeled after the German law, has recently been presented before Parliament. This is said to give greater security to the holders of concessions, and it is believed that it will tend to develop mining and attract foreign capital. The geographical position of Trebizond and of its mineral deposits, near the Black Sea coast, is favorable. Labor is abundant, wages ranging from 25 to 50 cents per day. One of the chief drawbacks is the lack of good roads and the entire absence of railroads, but this is one of the first things to which the new Government promises to give effective attention. In connection with the projected railroads, the coal deposits will have special interest and value. It is reported that at Erzeroum a company has recently been formed to develop the petroleum of Mamahatoun. Petroleum is also supposed to exist in the region of Van and on the Black Sea coast near Surmene. The Province of Trebizond is believed to be particularly rich in minerals. The indications are that there is much copper in this Province, as well as silver-lead, antimony, zinc, manganese, and coal. The adjoining Province has extensive and valuable coalfields in the Heraclea region. Few concessions have been granted for mines, but a considerable number of research permits have been obtained, and others are on the way. Most of the holders of permits expect to sell them. Unfortunately they generally put a high value on the claims.

HAINES DISTRICT, ALASKA.

Written for the MINING AND SCIENTIFIC PRESS
By W. A. SCOTT.

Haines is on the west side of Lynn Canal, 17 miles south from Skagway. It was first started as a mission for the Chilkat Indians, and eight years ago Fort William H. Seward was established there. In 1898 Haines was the starting point for those who went to Five Fingers and Selkirk over the Dalton trail. This trail went up Chilkat river 24 miles, thence westerly up the Klahini 30 miles, crossing the divide near the head-waters of the latter, to the drainage of the Alsek river. It was during the rush of 1898 and 1899 that the placer discoveries were made on Porcupine creek, a tributary of the Klahini, 38 miles from Haines; and at the same time a man named Hopkins camped for a time on the head-waters of the Klahini and named it Rainy Hollow, where important locations of copper leads were afterward made. Within the last two years the Alaska Road Commission, under direction of the War Department of the United States, has built a fairly good wagon road from Haines to Porcupine, and thence a few miles farther west to the international boundary; and the road commission of British Columbia is expected to extend this from the boundary to Rainy Hollow, a distance of about 18 miles, making a continuous road 56 miles westwardly from Haines. The Chilkat is a good sized, swift flowing stream, with a channel which widens to a mile where the river empties into Lynn Canal. The Klahini is much the same in character, draining a country of glaciers, jagged ranges, and sharp peaks, presenting a scene that is typically Alaskan. Going up the Klahini takes one in a westerly course as far as the mouth of Porcupine creek and on to the boundary line; from there it goes northerly to its source in the Rainy Hollow district. Before the international boundary was definitely established, the provisional boundary passed along the Klahini, where the former official stakes still remain. On the road to Porcupine the traveler passes through the Indian village of Klukwan, consisting of a Government school for Indians and a few frame houses. By the roadside are two brass cannon, which are said to have come into possession of the Chilkats years ago, but under what circumstances the cautious, secretive natives refuse to divulge.

The most important mining operations of this district are on Porcupine and McKinley creeks, the latter an affluent of the Porcupine. The Porcupine Gold Mining Co. has placer claims covering two miles of that creek. The original locations here were tested and worked to some extent by Harvey Wiley, Mix Brothers, and Fenley, who afterward sold to Jack Dalton. In May 1907 the Porcupine Gold M. Co. purchased the Dalton interests and acquired four additional claims. The creek, in its lower course, is bounded by limestone walls, and in its upper course cuts through slate. At the narrowest place the alluvial deposit is 75 ft. wide; in other places 300 to 1200 ft. The depth, from the surface to bedrock, is from 14 to 42 ft. The material grades from fine sand to coarse gravel and heavy boulders. The gold recovered is unusually coarse, occurring in rounded parti-

cles and small nuggets. Last year the company built a flume 5480 ft. long; at the intake it is 40 ft. wide by 8 ft. high. Below the centre it is 26 ft. wide by 6 ft. high, and 24 ft. wide at the spillway. It has an average grade of 1.65%. In the construction of the flume 2-in. spruce planks were used for the bottom and sides, the heavier material being hemlock. The stream carries from 23,000 to 54,000 miners' inches of water, the entire volume of which is turned into the flume. At the head of the flume is a 70-ft. dam, the crest of which is 4 ft. higher than the bed of the creek. Just below the dam are six gates for regulating the flow of the water. The main flume is tapped in three places, serving hydraulic operations at each. At the upper one is a penstock, diverting the water to a sluiceway; at this point is pit No. 1, excavated to bedrock, the gravel being lifted in scoop-shaped buckets to the hopper that sets over the sluiceway, a steam-hoist and derrick being used in this work. The boulders are lifted separately and piled on worked-out ground. The water is pumped from a bedrock sump by a steam-pump. At the next penstock below the requisite volume of water is diverted to a second sluiceway; a Pelton wheel is brought into use at this penstock, a shaft from which operates a hoist that lifts the placer-dirt from pit No. 2, dropping it into the sluiceway. This pit reaches bedrock at a depth of 42 ft. An 8-in. tandem centrifugal pump keeps it clear of water. Beginning 1000 ft. below pit No. 2, a bedrock sluice is being put in, which will extend upstream 2000 ft., and is being built 6 ft. wide by 4 ft. high. This will bring hydraulic giants into use on a considerable scale. At pit No. 2 a Lidgerwood overhead trolley-lift will be installed to supplant the derrick in handling the placer dirt. As soon as the bedrock flume is further advanced the entire plant can handle 1500 cu. yd. per day. As to values, it is claimed that tests and operations by Dalton and others showed a recovery as high as \$6.50 per cubic yard, and that clean-ups this spring showed an even higher content. But E. E. Harvey, general manager of the property, estimates an average value of \$3 per yard. Thus far the entire plant, including the flume, sluices, dam, hydraulic and steam-lifts, pipe-lines and giants, cost \$200,000, the main flume costing \$106,000. Operations began this year in May, and the length of the season is six months. At the source of Porcupine creek is a glacier, on the opposite side from Muir glacier. The period of high water is July and August. At present there are 80 men on the pay-roll, working two 10-hour shifts.

The Cahoon Creek Mining Co., under the management of Thos. Vogel, is conducting placer operations on McKinley creek, a stream that flows into the Porcupine two miles above the property of the Porcupine company. They are operating with a hydraulic lift on an alluvial deposit 60 ft. wide and about 40 ft. deep. This section of placer material is situated below an 80-ft. waterfall in the stream; the water for giants and sluicing is brought from Cahoon creek,

above the falls, by means of a 1½-mile ditch, a ¾-mile flume, and 2000 ft. of 12-in. pipe. This company has rich ground, employs 30 men, and makes regular clean-ups of placer gold.

Rainy Hollow district is about 4 by 6 miles in extent, situated at the timber line, at an altitude of 3000 ft., extending up to the summit that divides the Klahini from the Alsek drainage. The district is described as having limestone and schist country rock, with copper ore on the contact between the two. There are also numerous dikes of granite. The New York and Custer veins are said to be from 5 to 60 ft. wide, containing a good grade chalcopirite, with some bornite. Tests are said to show considerable gold and silver. The first locations were made by J. H. Chisel and M. J. O'Connor, of Haines,

Porcupine Gold Mining Co. Flume.

in 1898-9. The former sold his holdings last year to Walter S. Brown for \$25,000. The purchaser and associates expect to start development this season. He has four claims, each 1500 ft. square. There are 85 claims located in the district; among the other parties having interests there are Tim Creedon, S. J. Weitzmann, J. W. Burnham, Dan Sullivan, Mike Hasson, R. Kennedy, and Martin Conway.

Hornsilver, Nevada, 26 miles south-southwest of Goldfield, stands at an altitude of 5900 ft. above sea-level, on a gentle slope that opens northward into a broad desert valley and is enclosed on other sides by hills. The principal mineral deposits lie southwest of the town, within a distance of a mile, and are developed mainly by a single mine, from which shipments of ore aggregating in value about \$40,000 were made in 1908. The valuable contents of the veins are native gold and chloride of silver. The district has been described recently by F. L. Ransome of the U. S. Geological Survey.

THE TYUTICHA ZINC MINE.

Written for the MINING AND SCIENTIFIC PRESS
By CHESTER W. PURINGTON.

The Tyuticha zinc mine is situated in Siberia, 200 miles in a straight line northwest of Vladivostok, 24 miles from the mouth of the Tyuticha river. This river falls into a small harbor, about 30 miles north of Olga bay, situated in the portion of the North Pacific known as the Sea of Japan. Small steamers, making about 10 knots an hour, ply up the coast from Vladivostok, and afford communication with the mouth of the river in about 24 hours. The property consists of five full claims, equivalent to about 1200 acres. It belongs to Jules Brünner, of Vladivostok, who is of Swiss birth, but has acquired Russian citizenship. The claims were located in 1902, and patents obtained to them in 1903. The discovery is said to have been made by Chinese, who told Mr. Brünner about it in repayment for some kindness.

In 1902 the owner endeavored to interest London capital, and in 1903 the firm of Aron Hirsch & Sohn sent a German mining engineer to examine the property. This engineer determined that the ore was not in the main a silver-lead ore, as had been supposed, but that the deposit consisted of zinc silicate or calamine. It was further determined that the ore does not lie in a vein or bed, but is a massif or stockwerk, the size of which it was impossible to determine without extensive development. A considerable quantity of samples was sent to Germany. These, on being assayed, gave satisfactory results. Subsequent more elaborate sampling of the orebody, where it has been opened by development, has fully substantiated the first results. The average tenor of the ore, taking the mass as a whole, is 48% zinc.

As a result of the interruption due to the Russo-Japanese war, no serious work was done on the property until 1906. The thorough opening of the orebody has now established the fact that 200,000 tons of zinc ore of the character and value described, are present in a single mass. The calamine as taken out resembles chalcedony in appearance, and might easily be mistaken for it, except that it is softer. It is pearl-gray in color, translucent, and botryoidal in structure, frequently with concentric laminations. In the vicinity of the zinc mine, veins have recently been uncovered, some carrying argentiferous galena, others massive copper pyrite. The country rock of the vicinity is igneous for the most part. Granite, metamorphic greenstone, and Paleozoic schists are present.

On the basis of hauling with wagons to the seacoast the total cost of the ore delivered f. o. b. Antwerp is \$15 per long ton. The market price of the ore in Antwerp, reckoning on the lowest basis, is \$30. The present cost of wagon-haul is from \$6 to \$6.50 per ton, which cost it is planned to reduce to about \$1 per ton by means of a narrow-gauge railway and rope tramway, now under construction. Thus the entire cost of mining, hauling to port, and transporting to Antwerp will approach \$10 per ton. In mining, Che-Fu Chinese are employed at an average price of 60c. gold per man not 'found'. Owing to an understanding between the Nobel company and the

American powder trust, California powder companies will not sell the better grades of dynamite for delivery at Vladivostok. The price of dynamite at Vladivostok is 67c. gold per pound. Timber is available in inexhaustible quantity, as the region is heavily wooded with spruce, pine, oak, birch, and walnut. The orebody is, however, exposed on many sides, so that mining is practically all open-cut work.

The mine lies at an elevation of 1500 ft. above the sea, on the crest of the Sikota-Alin range. The upper station of the railway will be at an elevation of 700 ft. It is planned to connect the mine by wire-rope tramway $1\frac{1}{4}$ miles in length with that point. The narrow-gauge railway, with 20-lb. rails, will be equipped with two locomotives. It is being constructed by A. Koppel & Co., and will have a transporting capacity of from 80 to 100 tons daily, which capacity it is planned later to increase. There are now said to be 16,000 tons of ore ready on the dumps for transport by railway as soon as completed. The railway will be ready in August. Steamer transportation to Olga bay and vicinity is available throughout the year, and deep-draught steamers can enter. The zinc deposit is the first mineral discovery of any importance in the region, it being almost entirely unexplored. As foreigners are forbidden, except under onerous conditions, to hold or operate mines within 65 miles of the Pacific Coast of Siberia, it is not likely that development will be rapid, notwithstanding the great mineral possibilities of this region.*

The manganese industry of Brazil is at present in a depressed condition, according to consular reports. The exports of manganese ore in 1908 were valued at \$1,200,868, against \$2,442,984 in 1907. The exports of ore to the United States in 1908 amounted to only \$140,648, as compared with \$521,581 in 1907. According to Brazilian newspaper reports, the high freight rates on ore shipped by rail to the seaboard are the cause of the depression, but as a matter of fact the high cost of production shares equally with the freight in causing it. When the exchange value of the milreis is low, manganese ore can be profitably mined, but when the exchange value rises to 15d. (30c.), as at present, mining becomes unprofitable. Manganese ore is sold abroad at gold prices, while it is produced on a paper-currency basis. When an American dollar received for the ore was worth 4 milreis, the gold cost of the ore was about 25% less than when the dollar was worth only 3 milreis, the paper cost remaining the same. When exchange became more or less fixed at 15d. to the milreis, the exchange value became too high for profitable mining. Outside of the cost of handling the ore from the mines to the railway, on the railway to the seaboard, State taxes, etc., all of which are capable of the necessary modifications, there is no special reason why manganese ore should cost more in Brazil than in Russia. The present exports to the United States are running about the same as in 1908, and the outlook for a revival in the industry is not very promising.

*The data for the above were for the most part furnished by Mr. Kulm, the manager for Arthur Koppel Co. in Vladivostok, to whom my thanks are due.—C. W. P.

NOSTRUMS.

Written for the MINING AND SCIENTIFIC PRESS

By F. H. MASON.

What mining engineer has not, at some time in his career, run against nostrums in one form or another? Generally his mill-man is the worst transgressor; then come the blacksmith, and the engine-driver; even the cyanide-man and the assayer, especially if they are rule-of-thumb men, are often addicted to the fault. Those of us who were initiated into the mysteries of mining in Cornwall well know the care with which each assayer guards his own particular secrets that assure the success of his dry copper assays and, incidentally, often make his results differ from those of his fellows.

A poor mill-man finds it infinitely easier to remove the greenish gray hydrated oxide of copper, that sometimes forms on the surface of his plates, by the aid of a 'solution' than it is to prevent it from forming by carefully building up a thin layer of gold amalgam over the plate, and, in many places, each mill-man has his own particular 'solution', the composition of which he shrouds with an air of mystery. It is needless to say that when this hydrated oxide of copper (with which is sometimes found a little basic carbonate or sulphate) is being formed, its removal by suitable (or unsuitable) solvents, instead of its prevention by the proper amalgamation of the plates, will ultimately result in pitting and ruination of the copper. Often the superintendent is to blame from demanding that the plates shall be cleaned too 'tightly'.

When machine-drills are used for stoping some grease is, occasionally, sure to find its way to the mill, and then the mill-man runs for the lye-pot. The fact that mineral oil is generally used as a lubricant for machine drills, and that it is not saponified by caustic alkalies, has no influence on the average mill-man's desire to apply lye liberally the moment he detects the slightest sign of grease on his plates. Nor is the mill-man always content to allow the ravages of his ignorant fetishes to confine themselves to the plates. On one occasion I was visiting a mine manager, who had recently erected a new 20-stamp mill, and he complained bitterly that the cams and tappets were wearing abominably. He took me to see the mill, and I acknowledge that, for a mill that had been running less than two months, it was the sorriest spectacle I ever beheld. The cams and tappets were made of chrome steel, so that I knew that the fault was not with the metal, but adhering to them was a nasty black, sticky, gritty substance. After a great deal of trouble I obtained from the mill-man the recipe for his 'lubricant', the particular advantage of which, he assured me, was that if a little happened to fall into the battery it would not retard amalgamation. I have forgotten the exact proportions, but the ingredients were molasses, butter of antimony, and graphite, and, worse still, the graphite took the form of old plumbago pots ground up, which, it need hardly be added, contain a far larger proportion of abrasive than of lubricant.

The blacksmith's art has, from the earliest ages, been surrounded with mysterious recipes for quench-

ing fluids with which to harden steel. Pliny claimed that waters of certain rivers contained virtues not possessed by those of other rivers, and, if we follow the subject, we find such quaint recipes as, "Quench the red-hot steel in the blood of a young man 30 years of age, and of a sanguine complexion, being of a merry nature and pleasant." Robert Austen, in his 'Introduction to the Study of Metallurgy', regrets that so many recipes for tempering steel have been lost. The writer is inclined to disagree with his late revered professor and regret that so many remain. But, it may be argued, if these recipes have been handed down from time immemorial there must be something in them; and we reply, certainly there is something in them, but it can be reached by a quicker and less objectionable route. The gist of the whole thing lies in the conductivity for heat of the quenching fluid; the greater the conductivity the quicker will the steel be cooled and the less opportunity will there be for a re-arrangement of the molecules.

Take another instance; the engine-driver or stoker who 'doctors' his feed-water. He is the most dangerous of all, for he is not only endangering machinery, but life and limb. Among favorite remedies for the removal of scale we find oak-bark, oak and mahogany saw-dust, potato peelings, mineral oil, tallow, ammonium chloride, sodium carbonate, and molasses. The last is a panacea for all ills, including human ones, especially in the Maritime Provinces of Canada. Though some of these substances may, in a few instances, produce the desired effect, their addition to feed-waters is fraught with considerable and unnecessary danger. Then, too, these substances are usually added without any consideration of proper proportion to the amount of water that is being evaporated. The place to treat a feed-water is before it enters the boiler, and it should be only treated there after a knowledge of the composition of the water has been obtained. 'Monkeying' with feed-waters in the boiler—or outside of it—without a knowledge of the contained solids will sooner or later lead to disaster. The use of nostrums is the result of ignorance. Unfortunately there is a quantity of cheap literature, generally possessing some such title as 'Every Man His Own Mining Engineer', which, although it may contain some valuable information, also contains many recipes included with a view to filling the book. The rule-of-thumb mine superintendent, who has not the education to enable him to sift the good from the bad, devours all the recipes with avidity, and applies them, haphazard, to fit difficulties as they turn up. Unfortunately many of these nostrums appear to fulfill the functions with which they are credited, while at the same time they are insidiously doing work of destruction in another direction which may not become evident until the damage is irreparable. The underlings of such a superintendent frequently leave his service before they have seen the bad effects of the nostrums, and carry it to another camp.

Gold-bearing gravels in the Grant's Pass district of Oregon vary in thickness from a few to 50 ft., and their gold content also varies from 20 to 40c. per cubic yard.

GUATEMALAN MINING CODE.

*In view of the increased interest in mining possibilities in Guatemala, facilitated by the extension of the railway from Mexico into that Republic, the following extracts from the mining code will be of interest. The Law was issued as Decree No. 686, by President Manuel Estrada Cabrera, on June 30, 1908:

Article 1. The mineral substances and fossils occurring on the surface of the ground, or hidden under the soil, are, in respect to the regulations governing their exploitation, classified under three heads; namely, mines, clearings, and quarries.

Art. 2. Such places are to be considered mines where veins, beds, or pockets are met with containing gold, silver, platinum, quicksilver, lead, iron in veins or beds, tin, manganese, copper, zinc, bismuth, cobalt, arsenic, magnesia, antimony, molybdenum, or any other metallic substances, sulphur, coal, lignite, bitumen, alum, and sulphates with metallic base.

Art. 3. Clearings or loose soil containing minerals comprise alluvial soils containing iron, or pyrites capable of being converted into sulphates of iron; earth containing alum and peat.

Art. 4. Quarries comprise slate, building stone, marble, granite, limestone, gypsum, pozzuolana, basalts, lavas, chalk, marl, sand, flints, argill, kaolin, potters earth, all kinds of earthy substances, pyritic earths that are esteemed useful as fertilizers, whether worked by open-cuts or by means of underground excavations.

Art. 5. Mines specified in Art. 2 belong exclusively to the State.

Art. 6. Private individuals, by following the prescriptions set forth in this Code, may obtain the possession and ownership of mines, whatever be the origin and nature of the lode, and whether found on national, municipal, or private property.

Art. 7. Anyone who has acquired a mine is obliged to exploit and utilize it in accordance with the legal prescriptions.

Art. 10. Gold-bearing sands, alluvial and shifting deposits of iron, and other mineral products of rivers and placers open to the public, may be freely utilized by anyone, without need of a permit. If anyone should wish to treat such sands and substances in a permanent establishment, by means of machinery, or constructing works and buildings for the purpose, he may solicit the concession of a mining claim. For the demarkation and concession of the mining claim referred to in this Article, it is an indispensable condition that the party soliciting it prove that he has obtained the consent of the owner of the land on which he wishes to constitute the claim; or the fact of having paid the amount of the indemnity for the damage and injury that may be, or already have been caused to said proprietor. When the parties cannot come to an agreement, the indemnity shall be determined by the respective courts of justice.

Art. 17. In order to prospect or explore on cultivated or enclosed lands, it is indispensable to procure a permit from the owner or manager of the property. In case of a refusal on their part, the Alcalde of the place (local police authority) may on his authority grant the permit solicited, after giving audience to the parties interested, and experts, should he consider this necessary, or either party should demand it.

Art. 24. After a mine is formally registered, the land on which it is situated is subject to its (the mine's) right to occupy as much of the superficial area as may be necessary for its convenient exploitation, and in the measure that the development of the works may require.

Art. 35. A mining claim (or right) consists of a block of indefinite vertical depth, starting from the commencement of the subsoil, with a superficial area of 10 hectares, of rectangular form, and having on one side at least a length of 100 metres.

Art. 36. The discoverer of a new vein, pocket, or lode of any other description, containing any of the substances or precious stones enumerated in Art. 2, whether native or foreigner, is entitled to a concession.

Art. 39. The discoverer of mines on lands where no other has been conceded and registered, within a radius of 5 kilometres, is entitled to a concession of from one to three claims.

Art. 40. The discoverer, within a radius of five kilometres of a registered mine, is only entitled to one claim.

Art. 41. Excepting in these cases, in no other way can more than one claim be granted to the party who solicits it, but other concessions, without limit as to number, may be acquired by transfer of titles of ownership.

Art. 46. Every application for the denouncement or concession of a mine must be presented in the office of the Jefe Político of the Department where it is situated.

Art. 47. The application spoken of in the preceding article must express in the written petition: (1) The name of the petitioner and of his associates, if he has any, with place of residence and occupation. (2) The most prominent and distinguishing marks of the place where the lode for which he solicits the concession is situated. (3) Whether the mountain or land where the discovery is made has been exploited or not. (4) The nature or kind of substance discovered, accompanying a sample thereof to make it fully known. (5) The number of claims which the petitioner wishes to acquire, and if the land can admit them. (6) If the land is of national, municipal, or private ownership, stating in the last case the name and residence of owner. (7) The nature of the vein or lode discovered, the form of its lay (stratum), and the direction, more or less, that it crops out on the surface. (8) The name he proposes to give to the mine, and the names of neighboring ones, if there are any. (9) The place, date, month, and year of his application.

Art. 49. As soon as the record is made, the petition shall be despatched, the interested party being notified that within a term which must not exceed 15 days in case he has not presented together with the denouncement the necessary evidence, he shall furnish proof: (1) Of the existence of the lode in the place denounced, and that the sample presented was extracted therefrom, proving this by the testimony of two witnesses. (2) That he has erected visible landmarks or signs on the surface to distinguish the lode he has petitioned for, from any other. (3) If the mountain or hill where the discovery has been made is capable of admitting the extent of concession solicited.

Art. 59. After the measurement has been effected in the manner set forth in Sec. 5 of this Code, if found to be complete and legally correct, and after hearing has been given to the Government Solicitor, the corresponding title deeds of ownership shall be extended.

Art. 60. For the title deeds of the concession of a mine the interested party must pay previously \$200 to the National treasury.

Art. 119. A miner is the exclusive owner within the boundaries of his concession, and to an unlimited depth, not only of the vein or deposit denounced, but of all other veins, crossings, and mineral substances that may be found therein, as also of the water proceeding from the underground works.

Art. 124. Neighboring mine owners have the right to inspect an adjoining mine personally or by means of an engineer or expert nominated by them, or by the Judge in case of opposition, whenever they suspect that a trespass has been effected, or they fear an inundation or other damage of similar nature, or if they believe that by means of a geological examination they can acquire some data useful to their respective exploitations.

Art. 174. Companies consisting of at least three persons, substantiated by presentation of their articles of association, may claim a maximum concession of 60 superficial hectares if they are discoverers outside a radius of five kilometres of a registered mine; and also a maximum of 40 hectares if the mine discovered be within that radius.

*Translated for the Guatemala Post, Tipografia Nacional, Guatemala, C. A.

Electrically Driven Power Shovels.

The largest electrically operated power shovels ever constructed, having buckets of 4 cu. yd. capacity, and equipped with Westinghouse motors and automatic control, have recently been placed in the service of the Dolese & Shepard Co., of Chicago, for mining rock in its limestone quarries. The hoist movement of these two 110-ton machines is actuated by a 200-hp., 220-volt, series-wound, direct-current

Power Shovel Showing Swing-Boom.

Westinghouse type M. T. mill motor running at 415 r. p. m.; the thrust motor, controlling the movement of the dipper handle is an 80-hp. machine of similar type, while the swing-boom is operated by an 80-hp. motor. Each motor is controlled independently by Westinghouse type 'A' automatic magnetic switch controllers which secure the greatest nicety of operation of the heavy bucket. This form of control protects the motors from any heavy overloads which may result from the bucket striking solid rock or other obstruction, by opening switches to introduce resistance into the motor circuit. The control panels and resistances are mounted in the rear of the car, while the controller handles are conveniently placed under the hand of the operators.

The hoist and swing-boom motors are mounted within the car, as shown in one of the accompanying illustrations, which show the installation of the 200-hp. hoist motor in the foreground. The thrust motor is placed out on the boom, communicating its motion to the bucket staff through reducing gearing connected to a pinion engaging a rack on the staff. The power circuit to the shovel is completed through a feed cable, carried on a retractile reel on the shovel cab, and through the rails on which the shovel advances.

The shovel may also be fitted with a standard trolley for driving power for propulsion on ordinary electrified track. The machine may then attain a speed of five miles per hour.

Compared with the steam-shovel, the electric-driven excavating apparatus has been found to present marked advantages of simplicity, economy, and ease of operation. The hauling of water and coal is avoided, fewer operators are required to handle the machine, and a considerable saving of time is noted. For example, the cost of operating a certain electric shovel with 75-hp. hoist, 30-hp. thrust, and 30-hp. swing-boom is \$0.0164 per cubic yard of gravel, clay, and sand, while similar work performed by steam-shovels would cost from 3 to 4c. per cubic yard.

Coal Output of Missouri.

The total production of coal in Missouri in 1908, according to statistics collected by the U. S. Geological Survey under co-operative agreement with H. A. Buehler, State Geologist, was 3,317,315 short tons, having a spot value of \$5,444,907. In Missouri, as in Arkansas, Kansas, and Oklahoma, the coal-mining industry in 1908 was adversely affected more by the increased production and consumption of petroleum and natural gas in the Mid-Continent field than by the business depression. Natural gas from the eastern Kansas fields is now piped to Kansas City, St. Joseph, and Joplin, Mo., and to Atchison, Leavenworth, Lawrence, Arkansas City, Winfield, Wichita, Wellington, Hutchinson, Pittsburg, and Galena, Kansas. Oil from the same fields and from northern Oklahoma is being extensively used for fuel at Kansas City. These conditions have naturally affected the coal production of Missouri. The coal-mining industry of the State reached its maximum production, 4,238,586 short tons, in 1903. It decreased slightly in 1904, 1905, and 1906; rose somewhat in 1907, to 3,997,936 short tons; but decreased again in 1908 by 680,621 short tons, or 17.02%, in quantity, and by \$1,095,802, or 16.75% in value.

THE ASBESTOS mined and sold in the United States in 1908 was mined in Georgia and Vermont, and the total output of the various grades was 936 short tons, an increase from 1907 of over 42%. The total value of the output of refined asbestos in 1908 was \$19,624, as compared with \$11,889 in 1907, an increase of 64%. According to the report on

asbestos by J. S. Diller of the U. S. Geological Survey, the increase in value thus indicated is due to the greater production than ever before of chrysotile, the variety of fibrous mineral which is best adapted to textile processes and com-

Motors for Driving Power Shovel.

mands the highest prices. The main source of raw material, however, continues to be Canada, whence came all but \$1646 worth of the imports into the United States in 1908, valued at \$1,068,322. Much over half of the asbestos exported by Canada came to the United States. The United States leads all other countries in the manufacture of asbestos products.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS.

THROUGH YUKON AND ALASKA. By T. A. Rickard. 8vo., pp. 384, Ill., Index. MINING AND SCIENTIFIC PRESS, San Francisco, 1909. Price \$2.50.

There have been many books on Alaska, written from many points of view. In general they have been either tourist guides or scientific treatises. Much has been made of the mysteries of the country and the hardships of life in the Far North have been told with wearisome reiteration. Mr. Rickard's book is neither a tourists' guide nor a heavy technical treatise. It is a straightforward but lively account of a most interesting region and its people. It is a cheerful Far North which he gives us, whether he is speaking of Dawson, when the "women in white frocks, and a sunny cheery look in the faces of man and nature all bespeak the spring following a long winter," where "every patch of soil not covered by dwellings is green with new grass and bright flowers," or is describing Front street at Nome, which, he says, "has more character than the thoroughfare of any other American mining camp." "As Cairo is the meeting place of the Eastern and Western civilizations, so Nome is the spot where the people of the Arctic mingle with the invaders from the Temperate zone." "The Esquimo give color to the scene; the women in their pink and yellow parkas and wolverine hoods look like ladies on their way to a party; stalwart miners in high laced boots and stiff broad-brimmed hats recall Colorado and Nevada, and women dressed conventionally indicate that Nome has homes as well as mines." So we sit with him in the Royal Cafe and enjoy the silver salmon, reindeer steak, ptarmigan, blueberry pie, and the demi-tasse, and as the Havana cigar disappears we realize, with just a bit of sadness maybe, that our last frontier is about gone and Nome is really "no jumping-off place but on the highway of civilization from New York to Paris via Bering Strait."

The new land, however, has brought new problems in engineering, commerce, and government. These are all discussed thoughtfully. The great mines at Treadwell, the Yukon ditch, river transportation, the history of the anarchy at Nome, the pros and cons of a separate legislative body for Alaska, are presented fully but with that optimistic touch which is the best evidence that Mr. Rickard has got hold of the real spirit of the country.

It is a book to read if you are going North, and a book to read if you are staying at home. If Congress is to legislate wisely regarding our far northern Territory, the people at home must be informed regarding it. When they can get information and at the same time as much pleasure as the reading of this book gives, they are in luck. The word pictures and sober text are reinforced by nearly 200 illustrations of unusual beauty that make the country real even to the reader who gets no nearer Alaska than his own study.

MINERAL PRODUCTIONS OF ILLINOIS IN 1908. By R. S. Blatchley. State Geol. Survey, Circular No. 5, pp. 20. Urbana, 1909.

The figures collected by Mr. Blatchley show that Illinois produced in 1908, \$130,576,694, a decrease of 14.2% from the mineral output for the previous year. As was to be expected, coal showed the heaviest decline, falling from 51,317,146 to 47,608,161 tons. The general decline due to unfavorable industrial conditions was largely offset by increase in petroleum production.

EXERCISES IN SURVEYING FOR FIELD-WORK AND OFFICE-WORK. By John Clayton Tracy. 8vo., pp. 169, Index. John Wiley & Sons. New York, 1909. Price \$1.

This is a tremendously suggestive little volume; a stimulator. Professor Tracy is an excellent interrogator, and he has enquired into the details of surveying so curiously that his list of questions covers a multitude of points, many of which conceivably may never have occurred even to old practiced surveyors. The book is divided into sections dealing with every problem that can arise in plane surveying, giving equipment necessary, outline directions for the work,

necessary notes to take, and a series of questions relating to the minutiae of accuracy. The work is supplementary to the author's treatise on surveying, but it is of great value in itself. No surveyor could peruse it without discovering many things which he probably could not answer. It thus will serve to enable one to subject his own deficiencies to the test. It will also be invaluable as an aid to instructors in surveying.

FIRE-RESISTING PROPERTIES OF VARIOUS BUILDING MATERIALS. By R. L. Humphrey. U. S. Geol. Survey, Bull. 370, pp. 99, Ill. Washington, 1909.

This report contains the results of tests of thirty panels of various materials, made at the Underwriters' Laboratories at Chicago, Ill. The materials were subjected to direct heat for two hours and then quenched with water. The low heat-transmission rate of portland cement mortars and concretes was strikingly shown, as were many other facts of general interest and large practical value.

SUMMARY REPORT FOR 1908, MINES BRANCH, DEPARTMENT OF MINES, CANADA. By Eugene Haanel. Pp. 93. Ottawa, 1909. Price 10 cents.

A brief general statement of a large amount of interesting and valuable work.

SMOKELESS COMBUSTION OF COAL IN BOILER PLANTS. By D. T. Randall and H. W. Weeks. U. S. Geol. Survey, Bull. 373, pp. 185. Washington, 1909.

A consideration of principles, with results of Government experiments, and a chapter on central heating plants.

Commercial Paragraphs.

The WOOD DRILL WORKS, Paterson, New Jersey, has lately sold ten of its 3¼-in. drills to the California-Nevada Copper Co., at Juneau, Utah.

The CUTLER-HAMMER MFG. Co., Milwaukee, maker of electric controlling devices, announces the opening of a Philadelphia office, Room 1207 Commonwealth Building.

The hydraulic elevator being installed on the property of the Yukon Gold Co., on Bear creek, Yukon Territory, is of the Campbell type manufactured by the Hydraulic Supply Mfg. Co., Seattle, Washington.

THE FOOS GAS ENGINE Co., Springfield, Ohio, has recently received an order from the United States Government for six Vertical Foos engines, for use in the operations of locks on the Ohio river. Natural gas will be used for fuel.

THE *Technical Index*, published in Belgium, will be represented hereafter in the United States by the Geo. H. Gibson Co., Tribune Bdg., New York City. The *Technical Index* appears monthly and gives a systematic descriptive record of original articles appearing in over 200 engineering and technical journals and reviews, also indexing the proceedings of technical societies and technical books issued in all countries. It is stated that over 1000 original articles are indexed each month, covering all lines of engineering and technology. The American agents offer to send free sample copies upon request.

Catalogues Received.

THE JEFFREY MFG. Co., Columbus, Ohio, in its latest bulletin, No. 18A, describes the improved type of air-power coal cutter now manufactured by that company.

L. VOGELSTEIN & Co., New York, give the following figures for German consumption of foreign copper for the months January to May, 1909:

| | Tons. |
|-------------------|--------|
| Imports | 65,956 |
| Exports | 2,648 |
| Consumption | 63,308 |

As compared with consumption during the same period in 1908, of 68,893 tons. Of this quantity 60,353 tons were imported from the United States.

TELEPHONES are to be installed in Pekin by the Western Electric Company, and much pleasant talk regarding the matter is being exchanged.

REPORTS from Bulawayo, South Africa, affirm the discovery of gold deposits similar to the Rand banket, in the Abercorn district of British Central Africa. The new goldfield is said to cover an area six miles long.

DIVIDENDS were deferred on the stock of the International Smelting & Refining Company, contrary to expectation. It is thought, however, that present available income will warrant the payment of regular semi-annual dividends of 3 per cent.

TITUSVILLE, Pennsylvania, will celebrate August 28, the semi-centennial of the drilling of the first oil-well. Drake's 69-foot well, producing 40 barrels per day, would not be ranked as much of a producer in many of our oilfields today, but in its influence on industrial history it outranks them all. It was not the discovery of oil, for that was already known, but the development of satisfactory methods of drilling, which made Drake's work important.

MEXICAN politics seem to have experienced a fall in temperature. Gen. Bernardo Reyes has formally withdrawn from the candidacy for vice-president. Some enthusiastic Reyista clubs have declined to accept this decision of their leader, but the impression is that General Reyes is sincere in his determination. The transfer of Gen. Gerónimo Treviño to the third military zone, which includes the State of Coahuila, has been attended with enthusiastic ovations on the part of the people of Monterey. Meanwhile Governor Miguel Cárdenas of Coahuila steps aside, and Lic. Praxedes de la Peña is expected to take the post. Thus the Reyista influence seems to have subsided, with the patriotic connivance of the man himself.

GOLDFIELD is making preparations to entertain the American Mining Congress handsomely. The mines and the big mill of the Goldfield Consolidated are to be freely open to visitors. The State is collecting material for a special exhibition of its mineral resources and the whole of Nevada expects to keep open house. The opportunity to see new developments as well as to visit the historic Comstock near-by, will be unusual. Plans are under way for a large delegation from California. This is as it should be. Since the days when California miners flocked into the newly discovered Washoe district, the relations of Nevada have been peculiarly close to the chief Coast city. Many San Francisco buildings have been paid for

with gold or silver taken from Nevada mines, and many Nevada properties have been developed by technical skill and capital from the Coast. The relation has been one of mutual helpfulness. The meeting of the Congress in Nevada will afford an opportunity of cementing this friendship and promoting mutual acquaintance.

ANOTHER coruscating meteor has fallen ingloriously to earth out of the sky of mining high finance. The American Exploration Company has been the subject of anxious inquiries from many quarters; whoever has been approached by this concern has felt desire for further knowledge. Now the unconsumed remnant is being examined by the courts, and Mr. Henry I. Kowalsky seeks possession of the *reliquiae*. The company has been promoting mines near Yosemite National Park, California, and has caught in its trap many notable people in France, Belgium, and Spain.

SUCTION dredges have never proved successful in elevating gold-bearing gravel from river channels. Gold finds its way into clefts and fissures in the bedrock beyond the reach of the suction apparatus. Reports of favorable results with such appliances appear frequently in the public print, and novices are led to make unfortunate investments under the allurements of so plausible a method. Until someone shall devise an intake with intelligence enough to work its way into every inequality of the bedrock, suction dredges must continue to do the plebian work of deepening water-ways and filling marsh-lots for seaside resorts. Conditions favoring its application to auriferous gravels would need to be most exceptional.

MAZATLÁN, the largest port town on the West Coast of Mexico, will become a smelting centre, according to rumors which bear the mark of authenticity. The project has the backing of the Southern Pacific Company of Mexico. While reports fail to associate the two, it is reasonable to suppose that this enterprise must be connected with the old Mina Cobriza at Villa Union, thirty miles from Mazatlán. To erect a smelter in Sinaloa today, dependent upon custom ores and mattes would be anticipating development to such an extent as to invite disaster. In conjunction with a mine which could furnish raw material for the furnaces, however, a smelting industry at Mazatlán would encourage rapid exploitation of the copper deposits of the tributary district, that also yield considerable quantities of the precious metals. The Mexican Government has recently appropriated \$30,000,000 for the improvement of the harbor of Mazatlán, which should make it one of the finest ports on the Pacific. It is a land-locked bay of large size, but shallow, and obstructed by dangerous rocks at the entrance. The sum mentioned seems ample to create a harbor of the first class. With the shipping facilities to the north through Sinaloa and Sonora, and southeastward through Tepic and Jalisco, provided by the new railroad, this would become a natural focus for ores and other metallic products from a large area.

APPARENTLY copper quotations in future will depend upon actual demand for bona fide delivery of the metal. The New York Metal Exchange received a stunning blow from the committee headed by Mr. Horace White, that recently revealed "the forms that creep" in the under-waters of Wall Street. This particular Exchange met with so scathing a rebuke that action by the legislature to revoke its charter is regarded as almost certain. Reforms are consequently being made, in an effort to avert such an occurrence. A metal exchange is necessary. If this one cease to exist, another must fill its place. Reform of the abuses of a working institution are more practicable than the construction of a new one that shall perform its functions without friction. Among these reforms was the abolishment on August 2 of the quotation committee, which has in the past arbitrarily fixed the price of copper from day to day. The committee consisted of Messrs. L. Vogelstein, Harmon Hendricks, W. Parsons Todd, B. Hochschild, and Paul Konig, representation of the leading American and foreign concerns having been thus maintained. New rules for effecting deliveries of copper have been drafted, and it is expected that refinery receipts will in future be made negotiable.

Portland Cement and Monopoly.

Despite the prevailing business depression, and contrary to all estimates, cement production in the United States in 1908 showed a small increase. The total output for the year, according to figures compiled by Mr. E. C. Eckel for the United States Geological Survey, amounted to 52,910,925 barrels, selling for \$44,477,653. Of this, much the larger and more valuable portion consisted of portland cement, of which the output was 51,072,612 barrels, valued at \$43,547,679. This was an increase of 4.6 per cent in the output over the figures for the preceding year, but a decrease of 19.3 per cent in value. A closer analysis of the figures shows that the increased production came principally from the Universal Portland Cement Company, and subordinatedly from plants in the Middle West. In the Lehigh district of Pennsylvania and New Jersey there was an actual decrease of 4,217,299 barrels, so that the plants of the United States Steel Corporation and the independent plants through the West, not only absorbed all the new business but grew at the expense of the group which has long dominated the cement industry in this country. This is especially interesting in view of the determined efforts which have been made by the older companies to maintain their position.

The rapid development of the portland cement industry in the United States is one of the most striking features of our recent economic history. From an output of 42,000 barrels in 1880, 335,500 in 1890, and 8,482,020 in 1900, the production grew to 51,072,912 barrels in 1908. The growth from 1895 to 1905 was especially rapid, the output increasing in a single decade from 990,324 to 35,246,812 barrels. The reasons for this increase are many.

Portland cement was first made in the United

States in 1876 and exhibited at the Centennial Exposition, but in 1880, of the six plants which had been started, three had proved commercial failures. In 1882 when the Morell tariff bill was under consideration in the Senate, it was argued that cement should be put on the free list because there was no raw material for its manufacture in the United States, and a domestic industry could never be developed.

The early plants failed, apparently mainly because the processes then in use were too complex. The introduction of the rotary kiln, of coal-dust burning, improvements in fine grinding, the discovery of widespread materials, standardization of tests, rise in the price of lumber, education of the public in the use of cement, and the great industrial prosperity of the country, combined to develop the industry to an enormous extent and with remarkable rapidity.

Production on a large scale began in the East, and in the Lehigh district material was found of approximately correct composition to produce a superior cement. As its worth became recognized the prejudice in favor of imported cements was broken down and American plants multiplied. In 1890, however, the Lehigh plants produced 60 per cent of the total output. In 1897 they manufactured practically 75 per cent. From this position they dropped relatively, though their output increased absolutely, until in 1907 only half the output came from the Lehigh district, and in 1908 a trifle less than 40 per cent was made there.

The first plants were highly profitable, and the pioneer manufacturers desired to maintain as far as might be, their dominant position; a not unnatural desire when the long lean years of experiment and development between 1880 and 1890 are remembered. Cement making materials, as it happens, are widely distributed, and the market, while varying in density is also a universal one. Cement, furthermore, is bulky and heavy so that transportation charges at many points of delivery exceed manufacturing costs at the factory. All these factors work against any effective combination to control the industry and centre the manufacture at a few points. Under the leadership, however, of the Atlas Portland Cement Company, one of the largest and most successful of the Lehigh companies, combination was attempted. The North American Portland Cement Company was formed by consolidation of the so-called 'big six', the Alpha, Atlas, American, Lawrence, Lehigh, and Vulcanite companies. By acquiring stock ownership and building branch plants at strategic situations, the attempt was made to dominate the market. These methods were backed by the interchange of technical data, by systematic experiment, and by liberal and most judicious advertising, all of which were relied on to give the favored group the benefits realized earlier by the members of the German Portland Cement Manufacturers Association. These vigorous efforts were not without effect, but as the statistics already quoted show, they have not availed to build up a monopoly in the face of the large market, the widespread raw material, and a series of years of easy

money. The final reliance of the group attempting to build up a monopoly of this great industry has been the ownership of the Hurry and Seamon patents on apparatus used in burning coal-dust in the rotary kilns. There is some question as to the extent and validity of the claims made under these patents, and the matter has been in the courts for some time. Following one decision in favor of the patents a number of the independent companies surrendered and took out licenses to manufacture. Others have continued to fight, and testimony in additional suits is now being taken. The prize is well worth fighting for since the royalty, while small per barrel, would in the aggregate amount to a princely sum per annum. In a hard year, also, such as the last one, an addition of even a few cents to costs forms a handicap which may prove fatal. In 1908, the average price per barrel at the plant was 85 cents and much cement was sold for less. In Kansas City good portland went at 70 cents and at such prices even the smallest royalty would prove a serious matter.

At present there are three groups in the cement industry: (1) the so-called 'cement trust' which controls the old Lehigh district, and the patents mentioned, and is endeavoring to regain its dominant position; (2) the independent manufacturers, mainly in the Middle West; (3) the Universal Portland Cement Company, a subsidiary of the United States Steel Corporation. As has already been shown the two last named groups have been gaining on the first and older group both through prosperous and hard years. So far the Universal company has not been drawn into the patent litigation though there are rumors that it is about to take a hand. This would doubtless result in a battle royal.

The Universal company has had in some particulars the most difficult fight to gain its present position. Its product is made of granulated slag and ground limestone and the possibilities of the business are enormous, particularly in view of the present widespread tendency to combine steel and cement in modern construction. Prejudice, however, dies hard and it took years to convince the public that a true portland cement could be made of these materials. In 1900 less than half of one per cent of the total output of the country was made from slag. In 1908, 8.9 per cent or 4,535,300 barrels was so made, a truly magnificent technical and business triumph in the direction of using by-products.

As to monopoly or anti-monopoly of cement manufacture in this country, much may be said on both sides. It would be a national calamity to have this cheap and widespread building material, one of our main resources for future structural work, burdened unnecessarily. On the other hand a disorganized industry, the prey of swindling promoters and faced by extreme irregularities in prices, is a national liability. Sooner or later the consumer pays the bill and with a manufacturing capacity estimated at 103,000,000 barrels, and an annual output of approximately half that amount, it is not surprising that manufacturers are looking for some steadying influence.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

BEDFORD McNEILL is in Switzerland.

R. A. VARDEN has sailed for Colombia.

CURTIS H. LINDLEY is at Wardner, Idaho.

CHARLES BUTTERS is at Carlsbad, Germany.

J. ROSS BUET has left London for New Zealand.

F. A. GOWING has returned from Oaxaca, Mexico.

F. W. BRADLEY is at the Alaska Treadwell mine.

LEO VON ROSENBERG, of New York, is in Wyoming.

JAMES DOUGLAS will remain in England for the summer.

R. H. B. BUTLER is on his way from London to Mexico City.

W. MURDOCK WILEY has returned from Mexico to New York.

W. E. THORNE has returned from Brazil, and is at New York.

HORACE G. NICHOLS left British Columbia for London, August 13.

A. W. G. WILSON has been at Golconda and Bromptons Lake recently.

C. S. HERZIG is in London. He will return to Nicaragua in September.

RALPH ARNOLD has returned from Mexico and has been in San Francisco.

R. H. BURROWS is now with the Moctezuma Copper Co. in Sonora, Mexico.

A. C. REDDING has been appointed a Deputy Mineral Surveyor for California.

M. R. RICHARDSON is with the Mazapl Copper Co., Ltd., at Concepcion del Oro, Zacatecas, Mexico.

FREDERICK GRUNDY has returned to Los Angeles from examining mines near Needles, California.

W. R. CRANE has been visiting mining districts in the West and was in San Francisco this week.

GEORGE M. ROBERTS, manager of the Associated Gold Mines of Western Australia, is in London.

T. H. LEGGETT underwent an operation for appendicitis at New York, and is convalescing satisfactorily.

W. L. BOWBON has been appointed superintendent of the Gold Hill & Iowa mines at Quartzburg, Idaho.

D'ARCY WEATHERBE will return in September to the Rio Tinto mines, where he is one of the chief engineers.

ALFRED VON DER ROPP is expected in San Francisco, where he will hereafter represent the Consolidated Gold Fields of S. A., Ltd.

H. P. GARTHWAITE has returned from London, and has left for Copala, Sinaloa, and will thence proceed to Salvador, Central America.

JOHN G. WORTH is on a tour of inspection of the properties of the Worth American and Worth Exploration companies in Colorado, Utah, and Nevada.

S. E. BRETHERTON has been retained as consulting engineer by the Lodi Mines Co. of Nevada, for their smelter, which is designed to treat extremely rich ore, low in lead content.

FRANK L. SIZER is in Sandon, British Columbia, in connection with the Star-White extra-lateral right case, which has recently been decided in favor of the plaintiff after five years' litigations in the courts of Canada.

Obituary.

R. D. EVANS, who died recently at Boston, Massachusetts, was well known in mining circles. As president of the Yuba Consolidated Goldfields at Hammononton, he had much to do with the development of dredging in California, and his loss will be keenly felt.

General Mining News.

ALASKA.

(Special Correspondence).—In the Harris mining district, 12 miles from Juneau, an important discovery of gold ore was made late in June, 1908, by Thos. Dull and John Stevens, of Juneau, followed by the Wiley & Spaulding discovery in July. No secret was made of the find and specimens of rich gold ore were brought into Juneau and exhibited. This created an excitement, and since that time the country for miles around has been staked out, and every small launch and row-boat in Juneau and Douglas has been put into use by the prospectors. On the Salt Water Jack, and Stephens and Dull claims, visited by me, the owners have made good profits by ground-sluicing and 'mortaring' the oxidized rock. In this way the properties have paid for their own development. The vein runs through the country northwest and southeast in contact with a dike of diorite on the hanging wall side. The vein has a dip of about 15% to the northeast, and varies from 15 to 30 ft. in width. Fissure veins cut the main vein at frequent intervals, and here rich ore is found. The fissure veins cutting the main one run high in gold, but the ore as a whole may be considered low-grade. The country is hard to prospect owing to the fact that soil covers the surface and vegetation is abundant. Roads are being built, and work is being pushed on all the claims. The district is making a good showing and is attracting great attention. The Ebner mine in the Silver Bow basin has been sold, and a party representing the purchasers is now in Juneau making arrangements to start operations before the season ends. The mill will probably be enlarged, and mining carried on more extensively than heretofore.—The Mills property on Chichagoff island, of which W. H. Mills, of Sitka, is president, has a new 10-stamp mill installed, and, in co-operation with the Chichagoff Mining Co., has built a hydraulic power-plant which is to transmit power to the mines, a distance of five miles.—At Nevada creek, Douglas island, on the Alaska Treasure group, several buildings have been erected and a new tunnel is to be driven in from the bench a distance of 3000 ft. The work is under the direction of D. J. Argall.—The Perseverance Gold Mining Co.'s mine in the Silver Bow basin is operating steadily. The transmission wires are now being strung from the power-house on Sheep creek to the Perseverance. The power is to be generated by a large stationary gas-engine. A working bond has been taken on two mining properties in this vicinity by Pittsburg people, but the details are not made public. At Gypsum bay, a large force of men is engaged in mining the big gypsum deposit, under the management of T. H. George.—The Crystal Gold Mining Co., of Snettisham, is operating an excellent ore. Next spring the mill's capacity will be increased. Martin Olson, of Juneau, is the manager.

Juneau, July 21.

ARIZONA.

COCHISE COUNTY.

In April of this year the Copper Queen Consolidated Mining Co. replaced a portion of its timbers in drift 3-101 on the 300-ft. level with steel I-beams. These proved unsatisfactory in swelling ground and were replaced by sets of double-bracket beams. These also doubled under the strain, and are now being replaced by Oregon fir 12 by 12-in. timbers, which last 30% longer than either of the steel sets. The Sacramento shaft is being sunk from the 1500 to the 1700-ft. level. At the Spray shaft the shaft-house has been removed to facilitate ventilation. The precipitating plant of this company handling the water from the Czar shaft collapsed August 5 on account of the copper-water weakening the nails. The plant was 100 ft. square, 50 ft. high, and was damaged to the extent of \$5000.—The Mexico & Colorado railroad is completing a spur to the property of the Great Western Mining Co. at Courtland. The company has a large amount of ore on the dump ready for shipment. The first of this will be sent to the El Paso

smelter, as that plant needs this quality of ore to flux the material it is now handling.—Drifts from No. 11 cross-cut on the 300-ft. level of the Shattuck-Arizona have been driven over 500 ft. with raises over 50 ft. in ore.—The Bisbee Extension company is driving cross-cuts on the 400-ft. level in a low-grade oxidized ore. The company plans to sink to the 700-ft. level this fall.—A shot-drill has been started on the Geronimo property near Courtland.—The sum of \$14,330 has been raised for the further development of the Bermoudy-Turkey Creek property and a steam-driven compressor plant and five 2¼-in. drills added to the mine equipment.

GILA COUNTY.

The July output of the Old Dominion smelter was a trifle lower than the June, approximating 2,700,000 lb., 2,000,000 of which is credited to the Old Dominion mines. The cross-cut from the 14th level of the Old Dominion opened a body of smelting ore on that level of the Gladiator claim of the United Globe company. This orebody has been opened from the 10th level of the Old Dominion to the 14th level of the United Globe.—The double-compartment shaft which the Cactus Development Co. is sinking on the Pinto property near Globe is down 75 ft.—The cross-cut on the 600-ft. level of the Arizona Commercial Copper Co.'s mine cut an orebody at a distance of 350 ft. from the shaft.

Sacramento Shaft at Copper Queen Mine.

The Black Hawk winze is being sunk from the fifth to the sixth level in ore.—The power plant at the McGaw shaft of the Superior & Boston has been completed and the hoist is running satisfactorily.—The Sullivan shaft at the Cordova property is down 320 ft. A station is being cut on the 300-ft. level and cross-cuts will be driven to the ore.—The shaft of the Live Oak Development property is down 302 ft. and a station cut at the 218-ft. level.

SANTA CRUZ COUNTY.

The Industrial Mining Co., near Nogales, has resumed operations on its property which was shut down several months ago.

YAVAPAI COUNTY.

A drift has been started on the orebody recently cross-cut on the 500-ft. level in the Little Daisy mine of the United Verde Extension Mining Co. A winze is to be started shortly in the ore. J. J. Fisher is consulting engineer.—At the Derby mine, six miles west of Prescott, cross-cuts are being driven on the 300-ft. level. The company is to add 5 stamps to its mill shortly. George W. Young is manager.—I. F. Wilson has been employed by the Arkansas & Arizona Mining Co. to oversee the diamond-drill operations on its property. Considerable difficulty has been experienced on account of the hole caving and a portion of it had to be cemented, causing a loss of

time.—The Haynes Copper Co. has been forced to stop operations temporarily at its Jerome property on account of a heavy flow of water. A new pumping plant will be installed and work resumed. T. E. Campbell is superintendent.

YUMA COUNTY.

A vein assaying 14% copper and \$10 gold was intersected while cutting the station at the 100-ft. level of the Little Butte mine of the Little Butte Consolidated Mines Co. at Bouse. A 50-hp. hoist is being installed and ore-bins of 50 tons capacity built at the shaft. The average assay of the ore shipped from the mine is 10% copper and \$9 gold per ton.—A 74-ft. orebody was cut on the property of the Yuma Copper Co. in the Harcuvar mountains at a depth of 130 feet.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—The Bunker Hill paid in July two dividends of three cents per share, a total of \$12,000. The treasury contains \$65,850, and the mine is producing \$21,000 per month with 20 stamps.—The big vein recently cut at the 2100-ft. level of the South Eureka is said to be 18 ft. wide, assaying \$20 per ton.—The California Consolidated Mines Co. was recently organized with a capital of \$5,000,000 to operate the Keystone, Wildman, Mahoney, and other properties at Sutter Creek. Eastern people are chiefly interested.—A new cable 3050 ft. long was installed in the Kennedy shaft last week. The old cable has been moved to the north shaft. The main shaft is going down steadily and large quantities of excellent milling ore is coming from below the 3000-ft. level.—The Kennedy Extension has started to clean and repair the old shaft which is 1000 ft. deep. It is planned to sink it to the 1500-ft. point and cross-cut the vein.—The Crocker-Habrich-Holtz lease on Amador Queen is opening an excellent orebody. A carload running \$60 per ton has been shipped to the Selby smelter.—A number of small properties, that have laid idle for years, are being re-opened and actively exploited by eastern and southern Californian interests.

Jackson, August 9.

BUTTE COUNTY.

Lawrence Gardella is to install a dredge on the Mahle property. There are 220 acres in this ranch, all of which will pay the costs of dredging.

INYO COUNTY.

The Casa Diablo Mining Co. has just completed a three months run to test the efficiency of its plant and the cost of handling the ore. The foundations have been laid for a new motor and compressor, which should arrive at the mine in a few days.—The smelter at Keeler has been shut down for a few days to put a new water-jacket on the furnace.

NEVADA COUNTY.

The pipe-line to the McDonald ranch on Banner mountain has been completed and the steam-hoist is now in operation. From old surveys the channel is known to be near the surface at this point, so the company expects to cut the bedrock at an early date. S. T. Dille is superintendent.—The Black Swan mine at Mooney flat is to be re-opened. A 150-ft. shaft was sunk on the property several years ago, but the pumps were drowned out and the company stopped work. The machinery is being overhauled, and a larger pumping plant will be installed. A good body of gravel was cut by the shaft and short drifts run along the bedrock.—The foundations and framework of the Fairview mill have been started and a contract let to furnish the machinery.

SHASTA COUNTY.

A new dynamo was hauled to the hydro-electric plant at the Midas mine. The plant has been under construction for almost a year, and will now furnish power for the mine and mill, and lights for the town.—An oil seepage one mile south of Kennett has caused considerable excitement in that district and a number of claims have been

staked.—A contract has been let to sink the shaft on the James Sallee property at Old Diggings 250 feet.

SIERRA COUNTY.

M. I. Ish and associates have bonded the Big Boulder group of quartz and gravel claims 10 miles west of Downieville.—An adit is being driven to tap the channel on the Reese Ravine group. Allen Hubbard is in charge of the work.—The Oakland mine between Snake and Gold lakes is taking out some high-grade ore. Francis B. Voyle is in charge of the work.—Thomas Buckingham is repairing the mill at the Elsie mine and will run the ore from the Jim Crow through it.—The Haynes brothers are opening some excellent ore on their claims north of Poker flat.—The lower adit on the Bixby vein at Forest is in 130 ft. It will require 100 ft. more work to drive this under the shaft where the company will raise to the ore-shoot.

SISKIYOU COUNTY.

Representatives of Eastern capitalists are examining the Cariboo mine on Salmon river with a view to bonding it.

TRINITY COUNTY.

A company of Boston capitalists has been organized to dredge the farm of Clarey, Pane & Keenan near Trinity Center. Thirty holes have been sunk on the property, which is 500 yd. wide and one-half mile long, with satisfactory results. A small dredge operating on the property took out \$10,000 per acre recently. A large dredge will be constructed and the property worked on a royalty basis.—A new hydro-electric plant is being installed at the Headlight mine.

TUOLUMNE COUNTY.

The Tyro mine, one mile from Coulterville, is to be re-opened. There is a 10-stamp mill and complete surface plant on the property.—C. Leithold is working the tailing dump at the Mack mine.—The mill at the Mohican has been started and is running on high-grade ore from the mine.—Joseph Harten is taking some excellent ore out of the Little Wonder mine, upon which he has a lease.—The Shawmut mine has closed down to re-timber the shaft.—Drifts are being driven on the vein at the 100-ft. level of the Mangante mine near Jamestown.—Ore is being hauled from the Atlas mine to the mill at Tuttle town.—A cross-cut in the hanging wall of the Dead Horse mine, near Carters, cut a vein of free-milling ore 20 ft. wide.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An agreement has been entered into between the Argentine-Montezuma M. M. T. & T. Co. whereby the Argentine Central railway will use the Vidler tunnel for the running through of trains into the Montezuma mining fields in Summit county. Under the terms of agreement work will at once be resumed in the advance of the bore and within seven or eight months the undertaking will be completed. The Argentine Central tracks now lead to the portal of the adit, while a branch line is to be constructed from the summit of McClellan mountain to Gray's peak, a distance of seven miles. By running through the Vidler bore the distance to Keystone and Montezuma will be shortened by nearly 75 miles over that of the Denver & Rio Grande railway. As a result nearly all the ores of Summit and Lake counties will find a route through Clear Creek county.—The Calla adit is being driven steadily forward and drifts run on the Calla vein. Recent shipments assayed \$32 per ton in silver and lead. R. C. Vidler, of Golden, is manager.—Work was put under way this week in the construction of the new 50-ton mill for the Griffith Mining Co., and it is hoped to have the plant ready to put into commission inside of 90 days. The Malm process of ore extraction is to be installed. W. D. Hoover, of Denver, is manager.—Occasional shipments of smelting ore are being made from the Big Indian. The ore is of high grade, assaying from 4 to 5 oz. gold and 70 to 180 oz. silver per ton. Stopping has been started.—The 25-ton mill of the Crescent Mining & Milling Co. is now running night and day producing an excellent concentrate. The first shipment of ore was made this week to the local sampler and milled 65% lead, with 40 oz. silver per ton. It

is reported that shipments of smelting ore will be started during the next two weeks. O. Needham is in charge.—Cappel & Co., leasing on the Gem mine through the Newhouse adit, made a shipment of 13 tons of ore last week that milled \$24 per ton gold and copper. These lessees have a body of ore that is from 7 to 12 ft. wide, and from this time forward a heavy output will be made.

Georgetown, August 9.

GILPIN COUNTY.

Marshall D. Draper is organizing a company to build a custom mill and cyanide plant at Central City.

GUNNISON COUNTY.

Eastern capitalists have purchased the Victor mine and are developing a new vein as well as opening the old workings. The new vein assays 175 oz. silver and 25% lead with some gold and copper. George Denoon is manager.—P. J. Tischhauser, N. Schmuser, and John Davison, operating the Black Queen mine at Crystal under a five years lease, have opened a large body of smelting ore besides the milling ore already blocked out in the mine. The property is equipped with a 60-ton mill that is connected with the mine by an aerial tram.

LAKE COUNTY.

An aerial tram has just been completed between the Tucson mine on Iron hill and the spur from the Denver & Rio Grande railroad.—William S. Jones, leasing the Robert Lee mine on Fryer hill, cut a 10-ft. vein of zinc carbonate that assays 25% zinc with a small amount of silver.—The Leadville District mill is treating ore from the dump of the old Ballard mine.

OURAY COUNTY.

F. M. Jackson and E. C. Weatherby, operating the Old Lout mine in Poughkeepsie gulch under a lease, have started to drift from the face of the 1800-ft. adit to get under the shaft. This will give them 600 ft. of backs.—The Koehler adit at the San Antonio mine opened a second body of copper ore within 10 ft. of the body cut last week. The adit is 350 ft. below the bottom of the shaft and a drift will be started to get under that point.—The drift at the Calliope mine is opening a shoot of silver ore 3 ft. wide. The mill and entire surface plant were destroyed by fire. The loss is estimated at \$20,000.—Two feet of ore assaying 150 oz. silver per ton was cut on the Sutton group of the Slick Brothers Mining Co. on Mt. Hayden. The company is doing considerable work in the upper level of the property to demonstrate the advisability of driving an adit that will tap the vein at a depth of 800 ft.—A new compressor has been installed at the Atlas mine and the work is being concentrated on the drifts to connect the Atlas and San Pedro workings.—A new hoist has been installed at the Legal Tender mine and the shaft is being sunk to cut the contact.—The Jonathan mine near Ouray is being re-opened under the direction of John Donald.—Contracts are to be let for driving 1400 ft. of drifts and cross-cuts on the Camp Bird Extension property of the Amity Gold Mining Co. Lumber for houses and supplies for the winter have been ordered and the company will keep the mine running all winter.—A raise is being driven 300 ft. in ore to follow the ore-shoot from the lower to the upper level of the Thistledown mine. The vein is 3 ft. wide and assays \$10 per ton.

SUMMIT COUNTY.

Operations have been resumed at the Sallie Barber mine on the north slope of Mt. Baldy. The ore is lead and zinc and the property is in the centre of the group operated by the American Zinc Extraction Co.—The Reliance dredge in French gulch was shut down temporarily to install a new bucket-line. The work has been completed and the dredge is again in operation.

TELLER COUNTY.

The Vindicator Consolidated Gold Mining Co. produced 3000 tons of ore during July. Of this amount 2000 tons averaging \$42 per ton were mined on company account and 1000 tons averaging \$24 were mined by lessees. The high value of the company ore was due to the recent discoveries on the 1300 and 1400-ft. levels.—A cross-cut from the Em-

pire State shaft of the Isabella Mining Co. cut a 6-ft. vein of shipping ore at the 900-ft. level.—The School Section Leasing & Development Co., operating on the eastern slope of Bull hill, shipped 27 cars of \$25 ore during July.—Peter V. Wild and J. P. Hein shipped 25 tons of ore from the Bill Nye claim of the Copper Mountain Gold Mining Co. The vein was cut at a depth of 135 ft. on a contact of phonolite and granite.—Martin & Warmuth cut a 5-ft. vein of high-grade ore at a depth of 40 ft. on the Star of Bethlehem claim.—Ed. Gaylord, operating the Jerry Johnson mine under lease, shipped a 25-lb. gold brick to the Denver Mint.

IDAHO.

IDAHO COUNTY.

E. J. Comley and W. F. Johnson are driving an adit on their Hercules claims that will give 80 ft. of backs. A raise will be driven from the lower adit 220 ft. below and the ore handled through this.—A rich discovery has been made on the claims of John Harmon situated on the south fork of Clearwater river. The outcrop has been traced the length of two claims.

KOOTENAI COUNTY.

The Gold Ridge Mining Co. is building a spur from the Chicago, Milwaukee & Puget Sound railway to the Copper Prince mine in the St. Joe district. When the spur is completed a compressor and other mining machinery will be shipped to the mine. The company will also install a compressor and hoist at the Gold Ridge mine. D. Davis of Cœur d'Alene City is manager.

SHOSHONE COUNTY.

Thomas L. Greenough, president of the Snowstorm Mining Co., is authority for the statement that the company will discontinue its shipments to the smelter at the expiration of the present contract. The companies operating in this district feel that the railroad rates are excessive and a strong fight for reduction will be made.—A cross-cut adit is being driven on the Full Moon property east of Burke that will give 400 ft. of backs on the vein. W. R. Kelsey is manager.—The Wonder Mining Co. cut a 12-ft. vein of lead carbonate in its lower adit. A drift has been started to get under the shaft sunk in the upper portion of the vein that will give 480 ft. of backs.—An excellent shoot of copper-lead-silver ore was opened by the drift on the Big Chief claims in the Osburn district. The group joins the Polaris mine and is connected with the O. R. & N. railroad by a good wagon-road.—The drift from the 800-ft. level of the Hypotheek mine near Kings-ton has been driven 125 ft. on a vein of chalcopryrite and gray copper ore. In the upper levels considerable galena was associated with the ore, but this has completely disappeared with depth. Frank Guay is manager.—A lower adit is to be driven on the Torino group near Mullan as the upper drift has broken into a shoot of galena, carbonate, and native silver ore. Joseph Pella is manager.—The first shipment of ore from the Bear Top mine assayed 81% lead, 5 oz. silver, and \$1 gold per ton.

MICHIGAN.

A contract for 10,000 ft. of diamond drilling has been let by the Mayflower Mining Co. The holes will be drilled through the sandstone on the eastern portion of the property where it is thought to overlie the copper-bearing formation. A number of good cores were taken from holes on the western side of the property, but development work proved that side to be pockety and too low-grade to be economically worked.

MONTANA.

SANDERS COUNTY.

The cross-cut on the property of the Montana Gold Mining & Milling Co., near Heron, intersected a stringer of ore when in 45 ft. When the contract of 100 ft. is completed drifts will be run on this and the main vein. Charles Sawdey is manager.

NEVADA.

ESMERALDA COUNTY.

The orebody opened by the raise from the 360-ft. level of the Golden Daisy lease has been followed for 80 ft.

The lessees are shipping 5 tons of ore per day that mills \$120 per ton. Chas. D. Wilkinson is manager.—The Cherokee lease on the Atlanta property is sinking to the 600-ft. level where cross-cuts will be driven to the vein. The shaft of the Nevada Eastern lease is in vein matter but no ore of commercial grade has been opened.—A holding company has been organized by the officials of the Goldfield Consolidated for the purpose of taking over and operating the Consolidated mill, the Combination mill, and the Consolidated company's railroad. The company is capitalized at \$400,000 and is to be known as the Goldfield Mining & Transportation Co. At the Clermont shaft of the Consolidated the ore recently opened at the 730-ft. level continues to run above an average of \$30 per ton. Cross-cuts are being driven from the 860 and 1000-ft. levels to open this orebody.—The aerial tramway from the Little Florence shaft to the mill is completed and the foundations and concrete floor of the mill are ready for the installation of the new machinery.—At the Red Top Extension lease on the Bull Dog fraction a cross-cut is being driven toward the vein from the 475-ft. level.—At the C. O. D. Victor cross-cuts are being driven east and west on the 450-ft. level.

HUMBOLDT COUNTY.

The Darby custom mill at Seven Troughs has just completed a run on ore from the Buckhorn mine and has started on a consignment from the Seven Troughs property.—The shaft at the Peter Pan is down 200 ft. and a cross-cut started toward the vein. Ralph O. Giddings is manager.

LINCOLN COUNTY.

W. L. Undike of Bay City, Mich., has secured a bond on the Finsen Ray mine in the Highland district and is preparing to install a 5-drill compressor and hoisting plant.—The installation of a 60-hp. Fairbanks, Morse & Co. gasoline engine and 5-drill compressor has just been completed at the X-Ray mine in the Highland district. A cross-cut adit is being driven to intersect the vein system of the country. This will give 250 ft. of backs.—Cross-cuts from the 800 and 850-ft. levels of the Menda mine have opened a 5-ft. orebody that assays 45% lead and 70 oz. silver per ton. The shaft is down over 900 ft. and a cross-cut started from that level to the vein. John R. Cook is manager.

LYON COUNTY.

John Chrisman, of Salt Lake, has bonded the Constantine Brothers and A. J. Matt property in the Yerington district for \$20,000. A 90-ft. adit has opened a vein of carbonate ore that averages 6% copper.

NYE COUNTY.

(Special Correspondence).—At the Bonnie Clare mill 10 stamps are dropping on ore from the Rattlesnake mine and the remaining 10 stamps will be placed in commission within a few weeks. The vein at the Rattlesnake varies from 2 to 7 ft. wide and assays about \$50 per ton gold, silver, and lead. Most of the ore is coming from the 100 and 200-ft. levels.—Considerable activity is reported from the Lida and Gold Mountain districts, and a number of producing properties are being developed.—The Nevada Johnnie Co. has secured a controlling interest in the Bullfrog group at Johnnie for \$25,000 and will commence activities at once. A 100-ft. shaft cut a vein assaying \$8 to \$30 gold per ton.—A small vein of high-grade ore was recently discovered on the Barrel claim of the Nevada-Johnnie mine. It is reported that a small mill will be erected soon.—The Crown Point Globe is producing approximately \$3000 per month, with a one-stamp mill in action.—What appears to be a third channel has been cut at the Fairview placer claims at Manhattan. This is regarded as one of the important discoveries made since the opening of the camp.—Quartz mining at Manhattan is active. Lessees are operating at the Consolidated, Big Chief, Liberty, War Eagle, April Fool, Big Pine, Black Jack, Union No. 9, and Wolfstone. At the Thanksgiving the shaft is going down to the 550-ft. level.—The Independence and Nemo are working on company account.

Rhyolite, August 10.

The 50-ton custom cyanide plant recently installed by W. M. Armstrong on lower Shoshone creek has made several successful runs on ores of that district.—The Mayflower Consolidated Mining Co. is installing 10 additional stamps in its mill in the Bullfrog district and will enlarge the cyanide plant to handle the increased output. A station is being cut on the 500-ft. level of the mine.—The Pioneer lease is shipping 40 tons per day of \$50 ore to the Goldfield mills.—The Clothier-Gingles lease shipped 20 tons of ore. The lessees are working on a 4-ft. vein, the larger portion of which assays \$100 per ton.—The Hobo lease is sacking two tons of ore per day and has arranged with the Crystal Bullfrog company to put the ore through the Crystal mill.

WHITE PINE COUNTY.

(Special Correspondence).—It is estimated that the July production of the Nevada Consolidated mines was 180,000 tons of ore. For two weeks a daily shipment of 100 cars was maintained.—A second drill-hole is going down at Ely Central, next to the Puritan claim of Cumberland Ely. Explorations are demonstrating an immense body of ore.—At the Coppermines a hole is being put down near the Ruth mine. The former hole cut 120 ft. of ore before it was lost.—The Boston Ely shaft has cut a body of

Map of Eastern Nevada.

commercial sulphide ore at a depth of 855 ft. A vein of gold-silver-lead ore running \$20 to \$70 per ton is also being developed.—The Ely Copper Co. has let a contract to sink its mill shaft from the 200 to the 500-ft. level.—The hoist will be moved from the old Golden Gate to the mill shaft and 2000 ft. of drifts will be run from the bottom.—The Hulse Co. is developing the Ontario vein in the Hidden Treasure with good results. Assays run about \$40 per ton in silver and lead. The parent company is endeavoring to arrange for the active development of the copper lodes below the contact.

Ely, August 11.

The Campbell group of 25 claims at Steptoe have been purchased by James A. Wood, of Kansas City. A mill-site of 40 acres and an excellent water right is included in the sale.—Thomas F. Cole, James A. Snedaker, G. F. Piper, and Joseph B. Cotton, directors of the Giroux Consolidated, have just completed an inspection of that property and are authority for the statement that a concentrating plant and smelter will be erected at some point in the Robinson district to handle the output from the mine. The recent drillings on the property have shown the orebody to lie

in such a position that it can be mined with steam shovels. —The monthly payroll at the Ely camp was approximately \$250,000.

OREGON.

BAKER COUNTY.

Free-milling ore is being opened at three points in the Double Eagle mine near Greenhorn. George Kelly is manager.—N. W. Chapman and E. W. Cummings have purchased the placer claims of W. H. Turner in Bump gulch.—W. B. Fisher, of Salt Lake, has bonded the McDougall group of copper claims near Homestead.—F. C. Moore is making a report on the Golden Chariot mine for the stockholders. The mine has been unwatered and thoroughly sampled.

JOSEPHINE COUNTY.

Some excellent ore is being opened at the Golden Wedge property in the Galice district.—A lower adit is being driven to cross-cut the vein on the Oriole mine.

MARION COUNTY.

In the Santiam mining district a number of properties have reported new orebodies. A 6-ft. vein has been cut at the Lewis and Clark mine.—The Mineral Harbor mines are adding new machinery to their equipment to handle the increased output.—The Electric Mining Co. has been improving its surface plant.—At the Black Eagle the company is cross-cutting for the vein.—The Free-land Consolidated Mining & Milling Co. is also cross-cutting.—The Gold Creek Mining & Milling Co. is developing 4 large veins on its property.—A new wagon-road is being graded from Elkhorn to the proposed smelter site on Gold creek, which is a central distributing point for the mines of this portion of the country.

UTAH.

BEAVER COUNTY.

The shaft of the Cupric mine is down 340 ft. and has opened several stringers of copper ore.—A cross-cut is being driven on the 500-ft. level of the Cedar-Talisman mine to cut the vein opened recently on the level above.

IRON COUNTY.

Plans are being drawn for a hydro-electric plant for the Gold Springs Mining & Power Co. at Modena. C. A. Short is president of the company.

JUAB COUNTY.

A 50-ft. cross-cut from the 1000-ft. level of the May Day shaft opened a body of silver-lead ore that is of shipping grade.—The Eureka City Mining Co. has been organized to develop the ground under the Eureka townsite. Walter W. Fitch is president and a working capital of \$100,000 has been subscribed.—The grading for the shaft and surface plant at the Bradley group in North Tintic is now completed and a wagon-road to the property is being constructed. M. F. Sammon is in charge of the work.—The new machinery for the Tintic Standard has been hauled to the mine and is ready for installation.—The Scranton mine in North Tintic is shipping 2 cars of zinc to the Kansas plants and 2 cars of lead to the Salt Lake smelters per week.—J. H. Webber has secured an option on the Copper Jack property in West Tintic and will install a Keystone drill to prospect the ground.

SALT LAKE COUNTY.

The Richfield Consolidated Mining Co. has been incorporated to develop four claims in the West Mountain mining district. Thomas H. Quillen, of Bingham, is president.—The stock of the International Petroleum & Development Co. was listed on the stock exchange in Salt Lake City. This is the first oil stock to be listed on the local exchange.—The United States Smelting, Mining & Refining Co. is installing an electrostatic separator to clean its concentrate of zinc.

TOOELE COUNTY.

The output of the Consolidated Mercur Gold mines for July approximated \$60,000. This is somewhat below the average output owing to a collapse of three cyanide tanks due to the ground settling.

UTAH COUNTY.

The Mineral Flat Mining Co., near American Fork, cut a vein averaging 18 in. wide and assaying 44% lead, 80 oz. silver, and \$2 gold per ton. This drift gives 200 ft. of backs and an adit has been commenced that will obtain additional depth.

WASHINGTON.

CHELAN COUNTY.

Ray P. Davis and C. V. McDowell have bonded the Blinn property in the Red Mountain district.

FERRY COUNTY.

(Special Correspondence).—The Republic Consolidated Gold Mining Co. held its annual stockholders' meeting at Republic, August 4.—The Quilp Gold Mining Co. has leased the Quilp mine, in Republic camp, to S. L. Boyer, for a term of three years, the lessee to operate the ground north of the adit.—The Rio Tinto-Treadwell Mining Co. has an adit in 50 ft. and has let a contract to extend it 400 ft. farther. The company owns 11 claims in Curlew mining district, situated 3½ miles southeast of Curlew, in the copper belt. The annual assessment work has been kept up for 7 or 8 years and \$5000 has now been raised for development.—The Pleasant View Mining & Milling Co. has been incorporated to develop a group of 5 claims on Kettle river. Chas. Lefevre, of Kellogg, is the chief owner.

Republic, August 10.

OKANOGAN COUNTY.

(Special Correspondence).—The mill at the Nighthawk mine is operating steadily and producing a considerable quantity of concentrate. Fifteen men are employed in the mine and mill.—A deal has been closed by which Charles Gerhard has sold to Charles H. Brooks, of New York, a group of claims on Palmer mountain, which he has had under development for ten years.

Republic, August 10.

STEVENS COUNTY.

Frank Davy has leased the Bonanza property near Bossburg and is cleaning out the old workings. A hoist and compressor will be installed on the property and a new shaft sunk to the ore on the 300-ft. level.—A. E. Swanson is at the Calumet & Hecla mine on Deep creek to superintend the preliminary operation of the 40-ton concentrator plant just completed.

SPOKANE COUNTY.

A meeting of the creditors of the Idaho Smelting & Refining Co. is to be held in Spokane August 15, when plans will be submitted for the reorganization of the company.—The lower adit at the Tungsten King mine at Deer Park cut the vein at a point giving 190 ft. of backs for a distance of 1000 ft. Arrangements are under way to install a concentrator at the mine.

CANADA.

BRITISH COLUMBIA.

The Snowshoe mine is now shipping between 600 and 700 tons of ore per day to the Trail smelter. The mine is being worked by a large open-cut, the overburden having been stripped by an electric shovel.

YUKON TERRITORY.

A 5-stamp mill is being hauled from Dawson to the Lone Star mine at the head of Victoria gulch. Lionel Gilchrist is in charge of the work.

MEXICO.

CHIHUAHUA.

Firman Smith has been examining the Quebradillas mine near Parral for the Tennessee stockholders of the Vita Colorada Mining & Smelting Co. Plans are under way for reorganizing the company and starting the mine.—The Cherokee Goldfields, Ltd., has completed a 10-ton mill at San Julian. Gerald Hopkins is manager.

DURANGO.

E. E. Payne is opening a 2-ft. vein near Vilardena that assays 4% copper and 200 oz. silver per ton.

Special Correspondence.

LONDON.

Tronoh Mines.—Wheal Kitty.—South Crofty.—De Lamar Company.

The history of the Tronoh Mines, Ltd., during the last couple of years has been one of disaster. The company owns tin-gravel deposits in the Straits Settlements, and organized in 1901. For six years things went right so far as the shareholders were concerned; the output was regular, and the dividends satisfactory. Shareholders received in all 160% in dividends. It appears to have been a case of rich deposits easily worked, that could not help yielding a profit. The original vendors and promoters, Foo Choo Choon and E. G. Edgar, were left practically in sole control. Expenses of mining and of local management were high, and the Board of Directors had to take most things on trust. Originally the offices of the company were in Cornwall, for many people there hold shares. In fact the Thomases and Pearces were well represented on the Board, and still are. Two years ago there were signs of the mine becoming difficult to operate. The underground workings presented trouble, probably because proper care had not been taken to keep them in place and to cope with the floods which are common there. One engineer resigned and his successor recommended a change to open-cut mining. Machinery was bought to tackle the new method, but almost before it arrived its uselessness was acknowledged. The ground showed signs of slipping in all directions, and neither open-cut nor underground working seemed practicable. Another change was made in the administration. Mr. Edgar resigned his managing directorship and has now left the board. Harry D. Griffiths was appointed engineer, and he has studied the situation for about nine months. The mine is still being worked, and is producing tin concentrate, but exactly how long it will continue to do so is a problem not yet solved. The Directors have called in R. J. Frecheville for advice, to help determine whether the mine will have to be abandoned or not. The company owns other tin-bearing lands which have not been fully tested, and it is hoped that these will form an asset to fall back on. During the year 1908 the tin concentrate produced amounted to 1712 tons, and sold for £123,683, while the working costs were £101,073. These costs are high for a gravel mine in the East, and are unwarranted. The Board of Directors, since assuming full responsibility, has found difficulty in straightening the financial arrangements between the company and the late controllers, a circumstance which often occurs when promoters are allowed their own way in the management.

One of the most interesting ventures in Cornish tin mining at present is the Wheal Kitty at St. Agnes. It is only a small mine, but it succeeds remarkably well. It has been worked for many years, and was re-opened three years ago by J. H. Collins, who remembered what high-grade tin ore had been found there. I have from time to time referred to the mine in these columns. The results of working during the first six months of the current year have fully maintained the reputation of the mine. The stamps treated 6028 tons, and produced 120 tons of concentrate, which sold for £9990. The average yield was 44½ lb. of concentrate per ton, and the average price obtained was £83 per ton. This is higher than was current in Cornwall during the period, and shows that the ore is particularly pure. A profit of £2600 was made, and £912 was paid as dividend, which was at the rate of 7½% per annum on the issued capital. During the half year £3300 additional capital was subscribed for the purpose of extending the dressing plant and providing a new pump.

The South Crofty mine at Camborne, Cornwall, has issued a preliminary report for the first six months of the year. The figures are not fully audited, but are practically correct. The Directors believe in the issue of early information, as soon as the main items have been ascertained. During this period 29,152 tons of ore were milled, and the produce was 335 tons of tin concentrate, 72 tons of wolfram

concentrate, and some arsenic. The sales realized £34,056, and the working profit is given as £6187. The Directors estimate establishment-charges and other incidental expenses at £1000, and announce a net profit of £5187. All development charges during the six months have been included in the costs, though nothing is said about writing off past development and shaft sinking accounts or depreciation of machinery. Some of the English papers question the propriety of my criticisms when dealing with the announcements of this company. I pointed out that no provision for depreciation or writing off development amount was made, and that the small balance of working profit was not sufficient to show that the mine was on a paying basis. The margin of profit is much higher now, and has shown a gradual increase month by month, so it is safe to say that the mine has reached a paying stage.

The De Lamar company, operating in Idaho, has once more become a dividend payer. The old company paid £500,000 dividends on a capital of £400,000 within the years 1891 to 1901. Then it was decided to write down the capital to £80,000, as the mine had for some time shown signs of exhaustion. From 1901 to 1905 dividends totaling 87½% on the reduced capital were paid. After that came three lean years, when expenses were hardly met. The shareholders are therefore fortunate in having received a 10% dividend for the year ended March 31. During the 12 months in question, 42,116 dry tons yielded 15,825 oz. gold and 236,470 oz. silver. The costs of treatment have been greatly reduced during the year, being now \$9.41, as compared with \$11.47 a year ago. Some difficulty has recently occurred in connection with the silver sulphides at the lower levels, due to the presence of antimony. The engineer reports that no estimate can be given as to the life of the mine, but points to the continued discoveries of ore in all parts, a fact which gives him reason to believe that the mine will last for a considerable period.

WASHINGTON.

Tariff Revision.—Mineral and Metal Schedules.—Coal-Land Titles Annulled.—Tawney on Conservation.—Excavation at Panama.

William H. Taft is the man of the hour in Washington. For a time it looked as if Orville Wright, the aviator, was to have the spectacular arena all to himself, with his wonderful aeroplane, but Taft has triumphed! Wright won fame by going up into the air; Taft has won by refusing to go into the air. The sudden right about face of Congress on the tariff question to coincide with the views of Mr. Taft for a downward revision is the sensation of the city. When the Senate compelled the House to bow the knee in legislative matters, and the duties went up, up, higher than any aeroplane, Washington thought they would remain there. The men who write for Democratic papers were filling the columns with what the Democrats would do to the Republicans in the next election. But Mr. Taft has taken the tariff bill, schedule by schedule, and has informed the conferees just what is meant by downward revision in each instance. Reductions have been numerous.

Iron ore from 40 to 15c. per ton. Pig iron, kentledge, and spiegeleisen, from \$4 to \$2.50 per ton. Scrap iron and steel from \$4 to \$1 per ton. Aluminum, in crude form, from 8 to 7c. per pound; in plates, from 13 to 11c. per pound. Monzonite sand and thorite, from 6 to 4c. per pound. Lead acetate white, from 3½ to 3c. per pound; brown, gray or yellow, from 2½ to 2c. per pound. Nitrate of lead from 2½ to 2¼c.; litharge, from 2¾ to 2½c. per pound. Bituminous coal from 67c. per ton to 45c. Petroleum is placed on the free list. Boracic acid from 5 to 3c. per pound. Chromic acid from 3 to 2c. per pound; borax, from 5 to 2c. per pound; copperas, now dutiable at ¼c. per pound, is reduced to ⅓c.; sulphite of ammonia, now dutiable at ⅓c. per pound, is transferred to the free list. Sulphuric ethers are reduced from 40 to 8c. per pound; ochre and ochery earths, sienna and sienna earths, and umber and umber earths, from 1½ to 1c. per pound; orange mineral from 3¾ to 3¼c. per pound; red lead, from 2¾ to 2½c. per pound; white lead, white paint, and pigment containing

lead, from 2½ to 2½c. per pound; sulphur, refined or sublimed, or flowers of, from \$8 to \$6 per ton; plaster rock or gypsum, crude, from 50 to 30c. per ton; if ground or calcined, from \$2.25 to \$1.25 per ton; mica, cut or trimmed, from 12c. per pound and 20% ad valorem; and unmanufactured, from 6c. per pound and 20% ad valorem; all to 30% ad valorem, except mica plates or built-up mica, which are 35% ad valorem.

The increases were as follows: Chrome metal, ferrous-silicon, tungsten, and other new metals used in the manufactures, from 6c. per pound and 20% ad valorem; all to exceeding 15% ad valorem. Tungsten ore was made dutiable at 10%; a duty of 1c. per pound was put on zinc in the ore where it contains more than 20% of zinc. On zinc with less than 20% there is a lower rate. Oxalic acid is taken from the free list and a duty of 2c. per pound put on.

Attorney General Wickersham has discontinued the equity suits begun some time ago against the Utah Fuel Co. to annul title to 800 acres of coal lands in Utah valued at \$40,000. The discontinuance is made in view of the settlement between the Government and the representatives of the Fuel company under which the company agrees to pay the Government \$73,000, re-conveys the 800 acres to the United States, besides forfeiting \$14,400 paid in when patents were issued. The formal announcement of the discontinuance of the suits was made in the following official statement issued at the Department of Justice: "A few months ago, the Utah Fuel Co., a subsidiary corporation of the Denver & Rio Grande Railroad Co., pleaded guilty in the District Court of the United States for the district of Utah to an indictment charging it with having conspired to defraud the United States of 1440 acres of coal lands, and was fined \$8000. It also re-conveyed to the United States these lands, which are appraised at upward of \$50,000, and forfeited the original purchase price, and paid to the United States the sum of \$192,000 in settlement of its claims for coal taken from other lands which could not be re-conveyed owing to the fact that they were mortgaged to secure issues of bonds outstanding in the hands of bona fide purchasers. Subsequent to such settlement the agents of the Government became satisfied that the Utah Fuel Co. had illegally acquired title to other coal lands of the United States in Utah, and after examination of their report the Attorney General directed that suits in equity be brought to annul titles to such lands. Shortly after the commencement of these suits the representatives of the company opened negotiations for settlement, which resulted in an adjustment agreed to by the Attorney General and the Secretary of the Interior, pursuant to which the Utah Fuel Co. pays to the Government the sum of \$73,000, re-conveys to the United States 800 acres of coal lands now appraised at a value of about \$40,000, besides forfeiting the sum of \$14,400 paid to the Government at the time the patents were issued upon the lands. In view of this settlement, and upon payment and re-conveyance as above mentioned, the Attorney General has discontinued the suits. Only the lands described in the suits discontinued were embraced in the settlement. Further investigations are being made, and in case other land shall appear to have been illegally acquired, suits will be instituted at once to assert the Government's interest therein."

James A. Tawney, member of Congress from Winona, Minnesota, and chairman of the House Committee on Appropriations, made a vigorous defense of the attitude of Congress toward the conservation movement on the floor of the House the other day. He made the declaration that the national legislative body was being continually misrepresented in certain newspapers and magazines. "The most unjustifiable and reckless criticism of Congress upon this subject recently appeared in the *World's Work*, in an article written by Dr. Charles Richard Van Hise, president of the State University of Wisconsin," said Mr. Tawney. "Dr. Van Hise is now, and for several years has been, president of the University of Wisconsin. He has also served for many years as a member of the faculty of that institution, and was also a member of the Conservation Commission. This, however, has not been his only occupation, or his only source or revenue. For more than 26 years, or from 1882

until March of this year, he was an employee of the Geological Survey of the United States, and during that time drew from appropriations made by Congress as compensation for his services in the aggregate about \$50,000. Dr. Van Hise in this article assumes and falsely charges that the attitude of Congress has been one of hostility toward this movement, and invokes 'public condemnation' upon myself for having proposed the amendment to the Sundry Civil Bill in the last session of Congress which has made it impossible for any officers of the Government to pay any money from any appropriation to defray the expense of any commission not authorized by law." Mr. Tawney then went on to state that he had prepared an article for the *World's Work* in reply to that of Dr. Van Hise. The editors of that magazine refused to print his communication, making the statement that they did not think it would be good editorial policy. Mr. Tawney then asked that his article be inserted in the Congressional Record, which was done. In his reply, Mr. Tawney enumerates the appropriations given for the Department of Agriculture, the Forest Service, and the Geological Survey, and says that all these were for the conservation of the natural resources of the Government.

The War Department announces the total excavation of The Panama Canal to date as 78,905,501 cu. yd. There yet remain to be excavated 95,761,094 cubic yards.

MEXICO.

Zinc Barred by Tariff. — European Market for Zinc Ores. — Freight Rates. — Railroads in Western Chihuahua.

It is understood that shippers of zinc ore from Mexico to the United States will have until August 10 in which to get their shipments across the border, and there has been great 'greasing of the wheels' at the railroad offices, at the Federal assay offices, and elsewhere to get clearance papers made out and the cars away. Should the new rates go on as expected, it will certainly kill zinc shipments to the United States, at least for the present. The sliding-scale of the new tariff is but a miserable sop at the best, and it would have been far more agreeable to have had a flat rate of 1c. per pound duty instead of such an uncertain schedule, for ores under 25% zinc will not pay to ship from Mexico to the United States anyway. It is not believed that Mexico will suffer greatly, as there are almost as many buyers in the market for shipment to Europe as there were before for the United States. L. Vogelstein & Co. are now in the market as agents for Aron Hirsch & Sohn, Germany, instead of for the American Zinc, Lead & Smelting Co., as before; the Metallgesellschaft and the Compañía de Minerales y Metales will simply divert to their European representatives instead of shipping to the American Metal Co., as formerly. R. O. Ihlseng is also actively in the field, as well as others too numerous to mention. The object of Mr. Ihlseng's activity in the recent zinc discussion in the United States is now made evident. Among all the agitators for a zinc-duty in the new tariff-law none were more urgent and insistent than R. O. Ihlseng, who organized many of the zinc-duty clubs in Missouri, and, being a miner in a small way in the Joplin field, and a more than casual visitor to Mexico, his talks carried considerable weight, notwithstanding the fact that he had previously favored shipment abroad, and had always been a small buyer of zinc ores in the States for that purpose. As soon as the zinc-schedule of the Aldrich bill was decided upon, I understand that there was not one of even the smallest shippers of zinc ores in Mexico who failed to receive a letter from Mr. Ihlseng bidding on the ores for shipment to Europe. As yet the prices are far from being as favorable for shipments to Europe as they were to the United States, because of a somewhat higher freight rate. From Chihuahua, one of the principal shipping points, it is \$9.72 per metric ton to ship-side at Tampico, and 13s., or \$6.50, from there to Europe, making a total of \$16.22, while to the United States they paid \$3.78 to El Paso, and thence \$4.23, or \$8.46, to Kansas and Missouri points, a total of \$12.24. But it is hoped this may be adjusted between the

railroads and the steamship companies. Monterey, being nearer Tampico, has not this difference against it, though I have not the figures at hand. Undoubtedly the freight rates favor European points. The more optimistic are of the opinion that the duty on zinc will raise the price of the metal to that extent in the United States, and that shipment there may be resumed as before in the not distant future. The quicker liquidations and returns make it a more favorable market than the European.

Reports from New York are to the effect that F. S. Pearson has obtained for the Mexican Northwestern Railway of Canada, the Rio Grande, Sierra Madre & Pacific railroad, running from Juarez, Chihuahua (across the river from El Paso, Texas), down to Nuevas Casas Grandes, Chihuahua, a distance of 160 miles southwest from El Paso. It will be remembered that Pearson's company recently acquired control of the Chihuahua & Pacific railroad, running west and north from Chihuahua a distance of 180 miles, and soon afterward the Sierra Madre & Pacific running from the Chihuahua & Pacific northwestern terminus to Madera, about 40 miles farther, and toward Nuevas Casas Grandes, the terminus of the latest acquisition. As there remains a stretch of 115 miles to connect the two roads from Madera to Nuevas Casas Grandes, and thus give the company a through line from Chihuahua to El Paso, as well as an outlet through El Paso for the timber from the same 3,000,000 acres of pine-land, purchased when the Sierra Madre & Pacific railroad was bought, it is believed there will be no long delay in completing said connection. The plans of this Mexican Northwestern railroad are said to also include a connection finally to the west coast in either Sinaloa or Sonora. The company's movements are closely watched by all who are interested in the development of the western part of Chihuahua.

GUADALAJARA, MEXICO.

Hydro-Electric Plants.—Iron and Steel Industry. — Developments in Tepic.—Guanajuato Power & Electric Co —Lupita Mines.

The Chapala Hydro-Electric & Irrigation Co., which will transmit power generated on the Santiago river to the mining districts of Jalisco, Zacatecas, and Aguascalientes, has been launched with a capital of \$14,000,000. Fernando Pimentel, of Mexico City, is president. The company takes over the two plants that supply Guadalajara, and a 12,000-hp. plant under construction. It is estimated that under its concessions the company can develop fully 100,000 hp. Surveys for the transmission line which will carry current to the Etzatlan and Hostotipaquillo districts of Jalisco have been completed, and the work of erecting towers will be commenced immediately. The Tula iron mines in the Tapalpa district of Jalisco, together with 125,000 acres of land, and over 1,000,000,000 ft. of timber, have been sold to Massachusetts men represented by J. W. Dickinson, of Boston, for \$1,000,000. The Mexico Iron & Steel Co., capital \$5,000,000, will be organized to work the mines and build a modern steel plant and implement factory. The company will be headed by George H. Morrill, of Norwood, Massachusetts, and it is stated the investments will total \$1,000,000. The Tula mines have been worked at intervals for more than a century, and the iron is held to be the equal of the Norwegian product. The properties had been owned by Mexicans. The 150-ton plant of the Virginia & Mexico Mine & Smelter Corporation has been placed in commission. It is the first modern reduction plant in the Hostotipaquillo district of Jalisco. The company owns the Cabrera, Peralta, and America mines, and has an abundance of ore ready for the mill. The Mina Grande, a famous *antigua* of the Hostotipaquillo district, has been sold by the Dwight Furness Co. of Guanajuato to French interests, represented by Luis Chevrillon, of Mexico City. A company will be formed with French capital to re-open the old mine and develop it extensively. An adit that will cut the veins below the old workings is planned. The price of the property was \$75,000.

The Verdiana mine in the Ameca district of Jalisco has been bonded to James Moffitt, of Oakland, California, in the sum of \$25,000. Mr. Moffitt will start development work at

the close of the present rainy season. W. R. Tucker, of Guadalajara, owns the mine, which is a gold-copper property.

The mining districts of Tepic will not secure transportation facilities quite as soon as expected, as the work on the Southern Pacific extension has been suspended until after the rainy season. The forces had reached a point within 22 miles of Santiago Ixcuintla, where the Santiago river will be crossed, when the order for suspension was received. Rains have been heavy in that part of Mexico, and it was impossible to make satisfactory progress. Construction will be resumed in October or November on an extensive scale. Track is now being laid out of Tequila, the present terminus of the Southern Pacific line in Jalisco, and it will be continued to La Quemada, a point 20 miles northwest, which is near the place where the extension will enter the *barrancas* of the Sierra Madre. Train service will be extended to La Quemada in October, and transportation facilities will be then much nearer the mines of the Hostotipaquillo district. Waldo G. Meyers, a Mississippi man, who is developing the Zapote mine at El Liso, Tepic, will put in a stamp-mill, concentrators, and a cyanide plant and operate the machinery by water-power. The mine is a Spanish *antigua*, and an adit is being driven to cut the veins. The ores contain silver and gold. The El Dorado Mining Co. of Mexico City, which owns several properties in the Amatlan de Cañas district of Tepic, is making tests with a view to the erection of a smelter. The Brady mining interests of Goldfield, Nevada, will develop tin deposits on the Manuel Ruiz ranch in the Guanajuato district of Guanajuato. The ranch was recently sold to F. A. Cody, of Saratoga, California, and the Brady interests are concerned in the deal. The tin deposits have been worked by natives in a desultory way for many years. The 60-ton reduction plant of the Carmen Gold Mining Co. in the Guanajuato district is nearing completion and will be placed in commission early in September. The Carmen company is controlled by the Guanajuato Consolidated Mining & Milling Co. Within three months the Guanajuato Power & Electric Co., which made possible the mining revival in the old Guanajuato district, will commence work on a third hydro-electric plant. The company's first plant, an 8000-hp. installation on the Duero river near Zamora, Michoacán, was opened in October 1903, and last year a second plant, capacity 3000 hp., was built on the Angulo river in Michoacán. The third plant will be also on the Angulo river and will have a capacity of 10,000 hp. The company's power service is being steadily extended, and handsome dividends are being paid. Colorado men are principally interested in the company. The Lupita Mines Co. of Colorado Springs has resumed work in the Lupita mines in the Mascota district of Jalisco, after a suspension of more than two years. Hoisting and drilling machinery has been purchased and development work will be pushed. For several years the Lupita mines paid good dividends. Operations were stopped pending the acquisition of adjoining mineral ground, and this was secured some time ago. H. M. Sunde and relatives are clearing about \$3000 per month on shipments of high-grade ore from the San José de las Agujas mine in the Navidad camp of the Mascota district of Jalisco. This mine has been producing for several years, and some of the richest ore found in this portion of Mexico has been taken out of it.

BUTTE, MONTANA.

Butte Coalition.—Granite Mountain Sold.—Litigation Threatened.—Heinze and the Davis-Daly.—Smelter for Corbin.

The Butte Coalition Mining Co. will almost double its production of ore this year. Minnie Healy ground has proved very rich, and the Tramway has developed some valuable veins. The output of copper in 1909 should be between 30,000,000 and 35,000,000 lb. The company is getting out for reduction more than 1500 tons of ore per day. It is stated by a miner in position to know that development has been increasing the ore reserves greatly. There is a rich vein on the 1700-ft. level, which was recently opened, and some other veins have been cut by a drift which is headed for Minnie Healy ground. The latter claim is to be

opened on this level, a part of the extensive development carried on for a long period by the management with vigor and gratifying results. Although operations in the upper levels of the Minnie Healy are hampered by the fire, the management has planned a big campaign of ore-development and extraction for the ground below the 1500-ft. level.

It has been admitted that the North Butte company has bought the Granite Mountain claim. The fact was known here and asserted while being denied in the East. The company is still raising from several levels to connect with the bottom of the shaft on the Granite Mountain, which is 500 ft. below the surface. This will provide another working shaft. With connections with the Badger State shaft, a Boston & Montana company's claim near the North Butte company's property, it will be in a situation favoring extensive development and extraction. Although the Granite Mountain vein was of no importance on the levels opened by the North Butte company in the property since its purchase, when the shaft connections are made, the claim will be of value in the operation of the mine. In the Granite Mountain the Lewisohns, the former owners who sunk the shaft, and recently sold it to the North Butte company because they find nothing, evidently put their money on the wrong card, while they missed a good thing in selling the Edith May, whose orebodies have been rich and extensive.

There is talk of a controversy between James A. Murray and some of the Amalgamated companies over orebodies, including the claims of the North Butte company and those of the Bell mine. Murray owns the Ticon claim, lying in the midst of the North Butte company's claims and not far from the Bell, and miners to whom he has given a lease have sunk a shaft to the 800-ft. level, where they are driving eastward on the vein in the Ticon. Murray's contention is that this vein enters the Speculator claim on the dip, and that the North Butte company is taking his ore, instead of mining from the Edith May vein; in other words, that the Edith May vein, mined at low levels in the Speculator, apexes in the Ticon and not in the Edith May, northward of the Ticon. East of the Ticon is a claim belonging to the North Butte, and if Murray should be right, part of the vein would apex in this property and belong to the North Butte company. Murray may have some difficulty in showing that he is entitled to the ore in the Edith May, although his lessees are driving eastward for the purpose of discovering whether the workings of other companies are upon the Ticon vein.

The rumors concerning F. A. Heinze and the Davis-Daly estates have received a new turn by the statement that Heinze refuses to sell his interests in the stock because he objects to making a retreat while the charges against him in New York are unsettled. It is said that Heinze would withdraw from the Davis-Daly if he were not under a shadow, but there are people here who do not believe he would withdraw under any circumstances. Heinze has always been pugnacious and obstinate, and he probably would stick to his stock in the Davis-Daly at all hazards.

One of the managers of the Amalgamated mines states that the fire in the Anaconda is dormant at present, and that it has not given any trouble for about two months. It has been closed by bulk-heads, and the official said that it would give no concern till it should force its way out by an eruption of gas somewhere in the future. That is an event to be expected in the due course of time.

The Badger State shaft is now down 1300 ft. It is being sunk at the rate of 100 ft. per month, and will be carried to lower levels. The ore in the Corbin district is causing definite talk about a smelter for the district. Extensive mining has been done there for some time, and the widening activities of the camp, and the increasing developments of good veins and orebodies will make a smelter a necessity before long. Something that will stimulate operations in the Corbin country will be the electrification of the mines. This will take place soon. The Boston & Corbin company is mining three claims in the district, and it expects to secure electricity from the dams near Helena early in the fall, and then will run all its machinery with electric power. The Boston & Corbin is working three claims with a shaft 500 ft. deep, and most of its workings are in ore, while the

mineralization of the veins increases with depth. News from Corbin is of an encouraging kind, and all the owners believe it will become a big camp. Butte people hear that Phelps, Dodge Co. is about to retire from the mining field, and that the Cole-Ryan people will acquire its holdings in the Southwest.

TORONTO, CANADA.

Discoveries on Gillies Timber Limit —Provincial Mine —Cobalt Shipments.—Cement Merger.—Coal Miners Strike, Glace Bay.

The Gillies Timber Limit area is making good. One energetic private operator in the course of a few weeks has done what the officials of the Ontario Government with all the resources at their command, have failed to accomplish in three years. He has proved by actual operations that the deposits are immensely valuable. The successful miner is J. H. Waldman, of Montreal, who has made what is regarded as the most important find of the year on a property comprising about 92 acres, secured for a few thousand dollars, situated to the south of the Provincial mine. He set to work energetically a few weeks ago, employing a force of 70 men in trenching, the result being the discovery of what it is now the fashion to speak of as a 'silver sidewalk'. The vein has been stripped for a considerable distance, and is found to contain rich ore varying from 2 to 8 in. wide, extending from the Waldman property into the adjoining holding owned by M. J. O'Brien, where it has been found to widen considerably. This location of 40 acres was purchased by Mr. O'Brien a few weeks ago for \$10,500, and the selling price is now put at \$500,000. It will be known as the Young & O'Brien mine. The Waldman will be developed with all possible speed, the engineer in charge being Charles A. O'Connell, who has had a considerable Californian experience. Naturally this discovery, so soon after the sale of many Gillies Limit properties at prices that now appear ridiculously low, has created widespread interest and has greatly stimulated the activity of other purchasers. A feature of much significance is that the Waldman find is in the Keewatin formation, which has generally been neglected hitherto. A 60-in. vein, carrying 4500 oz. silver per ton, has also been struck in the same formation near shaft No. 54 on the Nipissing property.

The Provincial Government has decided to sell the Provincial mine after all, which, considering that they have been making a bluff at operating it for three years without any results of a character regarded as suitable for publication, is probably the best thing they can do. There have been repeated rumors that such a deal was in contemplation, but they have always been met with strong denials in official quarters. Premier Whitney has emphatically pledged himself, as a sop to the vigorous 'public ownership' sentiment of the Province, that the mine would be retained and worked as a public undertaking for the sake of revenue, but these pledges have now gone by the board. In fact, it almost appears, in view of the recent discoveries, as if the slackness with which operation at the mine has been conducted, had been intended to influence public opinion in favor of getting rid of a white elephant. At all events the loudly vaunted Government policy of running a mine in the public interest is a thing of the past, and the Provincial mine, covering an area of 30 acres, together with 20 other lots on the limit, amounting to about 350 acres, are offered under competitive tenders to close September 13, subject to a royalty of 10% on the output. Deputy Minister Thomas W. Gibson, of the Mines Department, has in preparation an official prospectus which will show the present condition of the mine and the result so far obtained.

The shipments for July from Cobalt amounted to 2715 tons, as against 3323 tons in June. The Crown Reserve held the first place as regards value, sending out seven cars of high-grade, two of medium, and two of low, while the La Rose was easily first, with three cars of high-grade ore, and 13 of low. There was a general slackening in both tonnage and value. Total shipments for the seven months ending with July were 18,006 tons, as compared with 25,361 tons for the whole of 1908.

Algernon P. Seymour has been appointed superintendent

of the Cobalt Lake Mining Co., the position being made vacant by the recent untimely death of E. L. Fraleck. A vein of 2½ in. on this property, discovered originally on the 130-ft. level, has widened at the 190-ft. level to 6 in., and the silver content increased to 3000 oz. per ton. The Silver Cliff joined the ranks of the shippers last week, with two cars of second-grade, which will be followed by a car of high-grade. A 100-ton concentrator will shortly be installed. The Foster mine, which has been doing poorly for some time, owing to the pinching out of the good ore, is to the front again, having struck 4 in. of rich ore between the old shaft and the Lawson line. The Ophir has obtained 4500 oz. ore at the 83-ft. level, the vein being in the Keewatin, and 3 in. wide. The directors of the Bailey have ordered the first half of a 12-drill compressor to be electrically driven by a 100-hp. motor. The Green-Meehan is another company which, after having run out of ore and become a non-producer for a long time is getting its second wind. Steady development has been rewarded by the recovery in a winze sunk 15 ft. from the 100-ft. level of the high-grade vein from which the first shipments were made.

The cement industry has for some time been in a bad way owing to over-production and undue competition, and the usual remedy of consolidation is being resorted to. Negotiations are on foot for a merger embracing the leading plants in Canada, with a proposed capitalization of \$25,000,000. While the highest rate of annual consumption amounts to 3,195,498 bbl., the producing capacity of the Canadian plants is over 10,040,420 bbl., having increased enormously during 1908. Though no definite arrangement has so far been made, it is regarded as certain that a merger will be effected, if not at present, in the near future.

The strike of the miners of the Dominion Coal Co., at Glace Bay, which has been in progress for more than a month, shows no signs of termination. Both sides continue firm, and while the company is slowly increasing its working forces, the defections from the ranks of the strikers have been comparatively few. The company has been able to make a good showing of shipments by drawing largely on the coal from the banks. The output for July was 203,982 tons, of which 136,000 was taken from the mine, the banks supplying the rest. The strike is likely to extend to the members of the United Mine Workers employed in the Spring Hill collieries, and by the Nova Scotia Steel & Coal Co. at Sidney. Resort was had in the latter cases to the Department of Labor and Conciliation Boards appointed under the Lemieux Act. But their findings were not satisfactory to the men, as in both cases they decided that the employers were justified in refusing to recognize the union on the ground that it was practically a 'foreign' organization, having its headquarters in the United States. As the great majority of organized workmen in Canada belong to international bodies, the far-reaching and significant character of these decisions can be realized. If all unions affiliated with international bodies are put out of court, any usefulness which the Lemieux Act may or could have had for the settlement of labor troubles is at an end.

ROSSLAND, BRITISH COLUMBIA.

Centre Star. — Federal Mining & Smelting Co. — Poplar Creek.

The mining situation at the Centre Star group of the Consolidated company is as bright now as it has been for some time. Big orebodies are being found at all parts of the property, the value of most of the ore being up to the average or better. A 14-ft. vein has been found on the sixth level of the Centre Star; the main vein on the War Eagle, as opened on the 500-ft. level, shows a large tonnage of \$16 to \$22 ore; a new vein of \$14 ore has been opened on the eighth level of the War Eagle, and two of the important Centre Star veins have now been found at 500 ft. in the Iron Mask and Idaho claims. The operations of this group earn from \$35,000 to \$43,000 per month for the Consolidated company. At the Trail smelter, owned by the Consolidated, a new copper furnace was blown in last week. This gives the plant four large modern copper furnaces and a big lead stack, or a capacity of approximately 2000 tons per day. The lead furnace has just been

fitted with a mechanical feed, which is a great time and labor-saver. This furnace treated 250 tons of lead ore one day last week, producing nearly 130 tons of bullion. The capacity of the lead and silver refinery is over 100 tons per day of the former metal, and it is the intention to make further additions without delay, as conditions locally point to heavy shipments from near-by mines from this time forward.

At the annual meeting of the Cambrian Mining Co. it was decided to place a further block of treasury stock to realize funds with which the steel-concrete shaft, being sunk in Moyie lake, will be put down to bedrock. This concern anticipates cutting the famous St. Eugene lead under the waters of Moyie lake. The undertaking has not proved an easy one thus far. A subsidiary company to the Federal Mining & Smelting Co., the Fort Steel Mining & Smelting Co., bought the mine, smelter, and equipment of the Sullivan Group Mining Co. at sheriff's sale. The Federal Co. held bonds in the Sullivan Group Mining Co. to the extent of about \$225,000. The outstanding indebtedness of the defunct company will be taken care of by the purchasers with a special stock issue, subject to recall at par. The smelter has been valued at over \$400,000, and there are 150,000 tons of ore in the mine that will average 15% lead and 6½ oz. silver. The Hattie Brown mine in the South Belt broke into the shipping list last week, sending a 30-ton car of select ore to the Trail smelter. The work of sinking the main shaft on the Le Roi No. 2, Ltd., goes on steadily; it is now down 100 ft. below the 900-ft. station. The new orebody on the 400-ft. level is proving good.

Considerable work is being done in the Poplar Creek district. The Gold Dust, Silver Bubble, Mayflower, Morning Group, Champagne, Marquis & Gilbert, and Golden Crest are among the claims on which work is now being done.

A lot of surface work is being done at the Snowshoe mine of the Consolidated Co. The ore deposits are being stripped preparatory to some 'glory-hole' operations. It is likely that shipments will be increased from this mine, now that the company has put another furnace in operation at Trail.

PIOCHE, NEVADA.

Las Vegas Smelter. — Salt Lake R. R. Troubles — Prince Con. Spur. — Nevada Utah. — Atlanta, the New Gold Camp.

Conditions in this camp are decidedly healthy, and the outlook highly promising. The Nevada Utah Mines & Smelters Corporation ran its product from the Day mine up to 200 tons per day, but have lately dropped to about 100 tons daily. The reason alleged for the decrease, and probably the true one, has been the rapacity of the smelters. The ore is exceedingly desirable for smelting purposes, but carries small amounts of silver. The large excess of iron and manganese in the ore is almost sufficient to cover transportation costs. The smelter refuses to pay for lead under 5%, although doubtless the amount of this metal recovered, if paid for, would cover mining costs. The officials of the Nevada Utah Co. have been so incensed at the treatment accorded them by the smelters that their Western manager was recently called to the company's office in New York for consultation. Upon his return he gave out for publication the statement that the money had been raised to erect an independent smelter near Pioche, which will purchase custom ores and furnish the desired relief. In this agitation for relief from smelter extortion W. A. Clark has taken a deep interest. As the builder of the S. P., L. A. & S. L. railroad, he has long desired to see a smelter built which would stimulate mining and augment traffic on his railroad. He has taken a special interest in Las Vegas, a logical place for a smelter, situated at the junction of the Las Vegas & Tonopah railroad with the Salt Lake line. Mr. Clark built the L. V. & T. railroad with his private funds, as a feeder to the Salt Lake line. Thus far it has been a financial failure. The Tonopah & Tidewater railroad, backed by A., T. & S. F. interests, made a shorter line to Los Angeles and took the business.

Mr. Clark, being a man of great force, wealthy, and hav-

ing been successful in the mining and smelting field, has been much disappointed at the lack of success of his railroad venture thus far. The first year after the Salt Lake line was built it was nearly destroyed by floods and was out of commission for several weeks. The following year it was washed out a second time. Again repaired and reopened, the floods once more descended and wrecked the road for a distance of nearly one hundred miles. The other disasters had been serious; this was appalling. It took two months of time to re-open the line, and is said to have drawn upon Clark's bank account to the extent of \$2,000,000. This hundred miles of road was re-built to defy the wrath of Jupiter Pluvius. Now Mr. Clark naturally wishes to see it a financial success. In the bitter controversy over location which occurred when the line was built Mr. Clark was outwitted by Mr. Harriman. The railroad novice proved no match for the veteran railroad man and financial manipulator. When the battle was over and the smoke cleared away, it was found that the Harriman interests held 51% of the stock, while to the Clark faction had been conceded the management for the first ten years. W. H. Bancroft, vice-president and general manager of the Oregon Short Line, and Harriman's right bower at Salt Lake, was first vice-president. It is said that the arrangement provided that the auditor and certain other officials should be selected by Mr. Bancroft. F. A. Wann, Clark's traffic manager, is an able man, and has tried hard to make the best of the situation, but it has been freely gossiped in railroad circles that the Harriman interests were trying to checkmate Clark at every turn and to make the Salt Lake line so unremunerative that he would become discouraged and let go. The ex-Senator, however, isn't built that way, and proposes to fight it out. He sees that the Gould system, from which he has derived most of his through freight traffic, is about to open a through line of its own to the coast, over which it can handle all the freight formerly turned over to the Salt Lake line. The only hope of making the Salt Lake line a pecuniary success lies in developing the local resources of the country through which it passes. Hence Clark's deep interest in the smelter situation. His mining engineer, E. W. Clark, of Ophir, Utah, has just spent a week investigating the ore situation and the prospects for a smelter somewhere on the Salt Lake line. W. A. Clark himself, recently returned from Paris, is now in Butte. A little later he is to come down to this district and personally grapple with the problem of how to make more business for his railroad. Meanwhile a line has been surveyed and tentatively located, connecting Pioche with some of its outlying mines and terminating at the Prince mine. This property, owned by the Prince Consolidated Mining & Smelting Co., has been shipping a little of its fluxing ores to the smelters for a test, and has sent out some sample cars of its better grade ores, but the waste of wagon transportation is too great and a railroad is to be built. The same lack of railroad sense which permitted Mr. Clark to be scooped by the Santa Fe has been manifested in the hesitation over building this line to the mines and the haggling over how much money should be contributed by the Prince Consolidated to pay for it, the amount thus advanced to be reimbursed in freight charges. The cost to the railroad company will be the same in the end, but the development of the region has been deferred, and the traffic which might have been created has been forever lost. Meanwhile the ten years tenure of office of the Clark officials is rapidly slipping away.

Unquestionably reliable reports from New York indicate that negotiations have been resumed for the settlement of the differences between the Nevada Utah and the Ohio Kentucky and the forming of a new company to re-open the old hill which was the scene of so much activity here in the early seventies. The Nevada Utah has begun to drive an adit from its ninth level toward its old Hillside mine, which was such a heavy producer during the seventies and eighties. This adit will be extended to connect with the workings of the Bristol Consolidated, and will be a vitally important factor in the ore production of that district. By the time it reaches the Hillside the Nevada Utah should be a heavy shipper over its narrow-gauge railroad. The Mendha continues to ship about a car a week, and lessees at the Bristol

Consolidated are still sending out an occasional car. The Pioche Metals Co. has joined the list of shippers and sent out a car from its Point mines. The Boston & Pioche has closed down, its president, A. W. Scott, giving out the statement that heavier machinery is to be installed and the shaft sunk to the water-level immediately. The Highland Mary mine, in the Highland district, has recently shipped a car. The Ely Valley Mining Co. is running with the usual force, but its manager, Edward Thomarson, is in London, where he has gone to confer with the other directors about important developments contemplated on that property. The company has several cars of ore on the dumps, but thus far has shipped none.

This region has a gold excitement which promises to develop into large proportions. The new camp has been named Atlanta, and adjoins the old camp of Silver Park which was started about 1868 by the overflow from the White Pine excitement. Its principal ores were silver chlorides in limestone, and were so rich that a large settlement was formed. When the stage line was put on from Hamilton to Pioche it went by way of Patterson, from which point a daily stage carried passengers and mail to Silver Park, 25 miles from Patterson and 45 from Pioche. Two Washoe mills were installed, which for a time found plenty of business. In 1872, when the mills of this region were insufficient to treat the ore mined here, some of it was hauled to Silver Park to be treated there. The decadence of both Patterson and Silver Park came before Pioche had seriously declined. Some of the best properties at Silver Park were secured by one Felix Knight, who worked them for years, hauling his ore to Pioche and shipping it out from here by wagon. In the early nineties Felix Knight died. The administrator of his estate sold his claims to Jesse Knight, the mining man of Provo, Utah, who has made such a phenomenal success at Tintic. There is said to be a close similarity between these Silver Park mines and those of the Tintic district. In October 1907 Mrs. Belle Fisher of Pioche went out to Silver Park to cook for the men who were doing the annual assessment work on Jesse Knight's unpatented claims. In her spare hours she wandered over the hills, prospecting. About two miles from the Knight camp she discovered some promising gossan. Taking out powder, fuse, caps, drills, and hammer, she drilled a hole, loaded it, and spit the fuse. At the first shot she broke rock which showed free gold, and then and there located four claims now known as the Atlanta group. Passing through intermediate ownership, these claims came recently into the possession of a syndicate which includes John L. Giroux and Elmer M. Bray, of Los Angeles, Frank Paul and others of Ely. The group is held under lease and bond for \$100,000, upon which a payment of \$3000 has been made through the assay firm of Marriage & Cosby of the Pioche Assay Office. F. Nugent Cosby of this firm was placed in charge. A shaft has already been sunk over 80 ft. At 20-ft. depth cross-cuts were run 20 ft. north and 15 ft. east. The rock from the cross-cuts and from the first 50 ft. of the shaft is said to have yielded average returns of more than \$10 per ton in gold. Below the 50-ft. level the ore is of higher value. No figures are given out, but mining men who have seen the ore estimate that it will run a hundred dollars per ton in gold at the present shaft-bottom.

A stage line has been established from Pioche to Atlanta. A town-site has been staked off, and lots have sold freely. The camp has a hotel with plenty of beds and is serving meals to transients; a restaurant; a store; and three saloons, besides a good many prospectors' shacks and tents. The gold is said to occur free in a belt of quartz lying west of and adjacent to the north and south dike of porphyry. On the west of the quartz belt is the limestone of the region. The quartz belt is said to have been traced for four consecutive miles and locations made the entire distance. It is claimed that free gold in what would be paying quantities has been found throughout the whole of this four-mile belt. The Atlanta Syndicate is jubilant over the result of its development and is taking bonds on many properties, making small initial payments. More than the usual amount of wrangling is going on over conflicting claims, and many lawyers are contemplating the situation with glee.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Single-hand drilling, when done by a skilled miner, in ordinary unoxidized ground, permits of 5 to 9 ft. of hole per 8-hour shift being drilled.

Periodicity in the maximum vibration of the piping leading to turbine engines is due to periodic synchronism between the rate of vibration of the piping and the number of pulsations of the steam admitted to the turbines.

Air-drills under show conditions have duties up to 10 or 12 ft. of drilling per hour in hard granite. Underground, with due allowance of time for setting up, picking down rock, etc., the duty is much reduced. In an 8-hour shift drills using two men ordinarily drill 20 to 40 ft. of hole. The one-man drills average 15 to 25 ft. per shift under actual working conditions.

Cyanidation of complex sulphide silver ores has attained a high degree of perfection in Mexico. The peculiarities of the Mexican method consist in fine grinding and agitation with air in tall tanks, known as Pachuca tanks, from the mining town where the system was elaborated. The pulp is then treated in vacuum filters for extraction of the solution. The Mexican method is also used at Tonopah, Nevada.

Calcium carbide when brought into contact with water reacts according to the equation:

The acetylene gas produced requires purifying, especially when used for illumination of houses. This is done with many substances, such as chromic acid, a mixture of bleaching powder and lead chromate, and acid cuprous chloride solution.

Geared hoisting engines are to be preferred for shallow depths and limited tonnage, on account of their low first cost. When great rope-speed is not essential they are fully as economical as direct-coupled engines. With greater depths and capacities speed becomes more important, and direct-coupled engines are necessary. For depths over 3000 ft. the starting load, on account of the weight of the rope, is greatly increased, and usually requires special consideration.

Sulphur dioxide (SO_2) is a pungent colorless gas, heavier than air (its specific gravity being 2.26). It is suffocating, and gives rise to most of the complaints which are made against smelter smoke, since it is carried to great distances, being a fixed gas, and being perceptible even when present in small quantities in the air. It is, however, not dangerous except in large volumes, and it has no effect upon vegetation. At ordinary temperatures it is absorbed in water, one volume of water taking up 20 volumes of the oxide.

Manganese ores are marketed chiefly at Pittsburg and Bessemer, Pennsylvania, and South Chicago,

Illinois. They are in demand chiefly for making spiegeleisen. Ores are sold on the basis of the unit (20 lb.) of manganese, a lower grade than 40% being unmarketable if the amount of silica exceeds 12%, and if the quantity of phosphorus is above 0.27%. The price per unit increases as the manganese content rises above 40%. Penalties are imposed on each unit of silica above 8%, and phosphorus is also penalized. The prices realized at the points of delivery range from \$5 to \$15 per long ton.

Sulphuric anhydride (SO_3) is evolved to some extent from the roasting of any sulphide, and is present in varying degree in all gases from the combustion of crude oil, coal, and from smelting furnaces. It is solid at a temperature of 58.64°F. , and is completely volatile at 114.8° . Sulphuric anhydride exists in two modifications, one being a liquid form which solidifies at 60.8°F. The condensation of SO_3 from gases is thus seen to present some serious difficulties, owing to the low temperature requisite. Attempts have been made to neutralize the SO_3 in furnace gases with zinc oxide, and the effort has met with some success. This is a logical solution of the problem if it can be made effective. The zinc sulphate produced would then be marketable as a paint.

Hydraulic mining is being conducted on a large scale at the La Grange mine in Trinity county, California, the annual output of gold being approximately a quarter of a million dollars. This mine is near Weaverville. Gravel mines are worked in many parts of Trinity and Siskiyou counties, the latter having over 100 such properties, yielding about \$217,000 per annum at the present time. Formerly the gravel mines of Siskiyou county produced more gold than all the other placer mines in California. The most important property today is the Quartz Valley Mining Co. at Greenview; other localities are Callahan, Cecilville, Forks of Salmon, Gazelle, Yreka, Seiad, and Hamburg. The restrictions of the anti-débris legislation do not affect the northern counties of California.

Prospecting with a diamond-drill can often be used to advantage, but two points must be kept in mind: (1) the sample obtained may be unrepresentative as to value, and, (2) deflection of the drill may carry it far away from its expected destination. A core-drill secures a small section, which is often ample for geological determinations, but the sample is only a small portion of a possibly large amount of ore, and may be either too high or too low in value. Two drill-holes passing through an orebody showed in the one case no payable ore, and in the other, 40 ft. of ore assaying \$80 per ton. Neither was right. The location, however, of the orebody is often, as it was in this case, of sufficient value to warrant the expense. In the mine a diamond-drill may often be used to prospect the walls and avoid expensive cross-cuts. There are various means of surveying drill-holes and allowing for the error introduced by deflection of the drill. At Johannesburg a copper wedge has been placed in the hole at a point above the orebody, and by deflecting the drill when re-introduced, served to enable two samples to be taken from one drill-hole,

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Gold in Eastern Nicaragua.

The Editor:

Sir—In your ‘Special Correspondence’ columns of the issue of April 24 appeared a communication relating to the gold mining industry on the east coast of Nicaragua. Some of the statements made apply to the interior of the country, but have no significance for other districts. Within the last few months considerable attention has been drawn to the gold mines of eastern Nicaragua, and for those desiring information the following facts may be of interest.

The area may generally be defined as extending north from the Escondido to the Wanks river and westward from the coast for a width of 100 miles. Mining activity has been confined mainly to the districts drained by the Pis-Pis river, a tributary of the Wanks, and the Banbana river, a tributary to the Principelea. Mining dates back for a period of 16 years, before which time some gold was exported that had been bartered from the Indians. It is said the Indians of the Siuna river were found using small nuggets of gold for sinkers of fish lines. A man named Schultz employed some Indians to wash gold, imposing upon each individual a daily task of filling one condensed-milk tin, for which the Indian received but 25c. in foodstuffs and clothes. The first mine to open up on a scale of importance was the Siempre Viva, which has now been producing 14 years. Other mines were opened from time to time, generally upon a small scale, building themselves up out of the profits, as in most instances the work was undertaken by men of small means, until at present there are nearly a score of properties being operated. The following table gives the gross value of the gold exports for each year ending June 30, since 1893:

| | |
|--------------------|-----------------------|
| 1893.....\$ 88,522 | 1902.....\$273,616 |
| 1894..... 109,477 | 1903..... 378,866 |
| 1895..... 94,369 | 1904..... 534,371 |
| 1896..... 137,929 | 1905..... 421,046 |
| 1897..... 169,565 | 1906..... 463,110 |
| 1898..... 254,840 | 1907..... 557,550 |
| 1899..... 229,262 | 1908..... 499,165 |
| 1900..... 301,127 | |
| 1901..... 234,383 | Total.....\$4,747,208 |

The types of deposits comprise veins and impregnations of irregular shaped bodies of decomposed porphyry. Only recently has one of the mines reached a considerable depth. The deposits are usually oxidized for a vertical depth of 300 to 400 ft. Above the water-level, from which all the gold so far has been produced, the ores are usually friable, with a tendency to being clayey. Light stamps are used in some of the mines, especially where the ore is more than usually hard, but in the greater number of deposits the ore is too soft for stamp-milling, and in such cases 3½ to 5-ft. Huntington mills are employed, and are particularly well adapted to the ore.

Surface disintegration of the outcrop often results in the formation of a mantle of rich soil spreading outward from the orebody as a centre, covering much more surface than the original outcrop. This is locally called a *manta*. These *mantas* are often of great extent, and the material being in a fine state of subdivision, permits recovery of the gold by most simple means, such as sluicing; and from the working of the *mantas*, especially if rich, sufficient returns are obtained to explore the orebody or even pay for the erection of a small milling plant. Narrow, isolated, well-defined veins are frequently found, known as *hilos*.

By far the greater number of the known ore deposits are situated in hills, so that the ore may be mined by open-cuts, with a system of adit-levels below for tramming out the ore, which is broken down into the mill-holes rising from the adits to the bottom of the cuts. No hoisting has been done to any extent

Map of Nicaragua.

in any of the mines, nor has the water-level been reached, except in one or two instances. Systematic development and creating an ore reserve are practices unknown in the district. Stoping has been done to a small extent, but entirely from one or two shallow levels driven along on the strike of the deposits; never at a deep level. Some of the mines, where work has been carried to the vicinity of water-level, show the presence of sulphides, galena, blende, copper, and iron pyrite. Usually there is little difference in value between the oxidized ore near the surface and that from the lower limit of the zone. Not enough is known of the deposits at or below water-level to make any statement as to the change in value of the ore. At the Santa Rita the sulphides contain about as much gold as the surface or oxidized ores. This deposit is a mineralized mass of decomposed porphyry, the ore at water-level being a mixture of chalcopyrite and pyrite, the gossan cap of which, some 400 ft. deep, is being worked for gold.

The metallurgical operations are most simple. Amalgamation alone, or followed by cyanidation of the coarse tailing, is the practice at all places except Santa Rita, where the coarse sand is separated from the tailing and re-ground, thence to pass over

amalgamating and blanket-tables. The tailing from this operation contains too little gold to pay for further treatment. Some of the mines are now reaching the deeper zones of ore, requiring much greater skill and more elaborate methods to economically win the gold content. The following is a list of the mines now operating that are provided with milling facilities:

| Mine and District. | Stamps. | Tons. | Power. |
|--------------------------------|---------|---------|-----------------|
| PROSPECTING MILLS. | | | |
| El Paraíso, Ococonwas..... | ... | ... | |
| Rosa Lee, Pis-Pis..... | ... | ... | Water. |
| Morning Star, Pis-Pis..... | ... | ... | |
| STAMP-MILLS. | | | |
| Colonia, Pis-Pis | 5 | 15 | Water. |
| Constancia, Pis-Pis | 5 | 15 | Water. |
| Josefina, Pis-Pis | 6 | 18 | Steam. |
| Concordia, Pis-Pis | 10 | 25 | Water. |
| *Siempre Viva, Pis-Pis | 20 | 60 | Hydro-electric. |
| *Topaz, Rama | 20 | 60 | Water. |
| *Lone Star, Pis-Pis | 30 | 100 | Water. |
| 3½-Ft. HUNTINGTON MILLS. | | | |
| Minnesota, Banbana | 1 | 15 | Steam. |
| San Antonio, Ococonwas..... | 1 | Closed. | Steam. |
| Monte de Oro, Siuna..... | 1 | Closed. | |
| Mars, Pis-Pis | 2 | 30 | Hydro-electric. |
| *Bonanza, Pis-Pis | 8 | 120 | Hydro-electric. |
| 5-Ft. HUNTINGTON MILLS. | | | |
| La Luna, Ococonwas | 1 | 30 | Steam. |
| *La Luz y Los Angeles, Pis-Pis | 2 | 75 | Steam. |
| Monte Carmelo, Banbana..... | 3 | 120 | Steam. |
| Santa Rita, Banbana. | 5 | 250 | Steam. |

The Terciopelo mine, on the Banbana river, is being equipped with log-washers to disintegrate a gold-bearing clayey *manta*, the gold to be recovered by means of sluices and Pierce amalgamators. At all the above-mentioned mines the gold is recovered by amalgamation. Those mines equipped with a cyanide plant for treating the sand are marked with an asterisk (*).

Where a supply of water can be obtained for power the first cost of a milling plant and the expense of operation is greatly reduced. The Pis-Pis district is more favorably provided with water-power than the Ococonwas and Banbana districts. The largest hydro-electric plant is that of the Siempre Viva mine, situated below the falls of the Pis-Pis river. This company rents power to some of the neighboring mines, and if the total power the falls could be made to supply were availed of, power enough might be generated to run nearly all the mines of that district. Where a steam-plant is required, there is usually an abundant supply of wood for fuel, which, if a long haul is not required, can generally be laid down at the boilers for \$3.50 U. S. Cy. per cord.

During the dry season many mines depending upon water-power are obliged to close part of their plant, and during exceptionally dry weather there often is a shortage of water for milling purposes, even at those plants where steam-power is used. In most instances a pumping station placed at the river-side could be utilized during the dry weather without causing a prohibitive increase in operating expenses.

The country is sparsely populated; but so far no one has been annoyed to any great extent by shortage of labor. Mosquito Indians, Nicaraguans, and blacks from the West Indies comprise the available labor supply. Should operations at the mines ever exceed the supply of labor the country can furnish, abundant labor could be brought in from the West

Indies. The part of Honduras bordering on the east of Nicaragua is very sparsely populated, and could not be counted upon as a source of labor. The interior of the country might furnish recruits, but as a rule the natives do not care to come down to the lowlands of the coast. Typical rates of wages are given in the following table:

| | Soles per diem. |
|------------------|-----------------|
| Timber-men | 3.00 |
| Drill-men | 2.50 |
| Miners | 2.00 |
| Trammers | 1.75 |
| Mill-men | 1.50 to 300 |
| Fire-men | 300 |
| Carpenters | 2.00 to 6.00 |

The mines provide lodging and board, for which no charge is made to employees. The cost of boarding varies between 40 and 80c., U. S. Cy., per diem. Almost all food-supplies are imported from the States. The laborers' meals comprise rice, beans, bread, coffee, and fresh meat. Most of the mines have made no attempt to cultivate their territory with a view to raising their own foodstuffs. The soil is generally productive and several crops per year may be realized. The natives would be content with what the soil could produce, and by cultivation of the land, imports of foodstuffs could be reduced to lard and such supplies, that cannot be grown. The labor is very efficient—the best I have seen south of the Rio Grande—but the malarial fever of the coast makes it necessary for most of the mines to keep on hand more laborers than ordinarily would be required, to replace those who lay off from sickness. The natives, especially the Indians, are nomadic, and rarely stay in one place more than three months at a time. Silver money is in circulation, paper being unknown. The current rate of exchange is 38c., U. C. Cy., as the equivalent of one sol. Coinages of all the Central and South American Republics pass at the same rate. The amount of coin in circulation is far from enough to supply the mines; liquidation of laborers' accounts has to be made in greater part by means of drafts on the merchants, the laborers exchanging them for merchandise and such cash as they can get.

The costs of mining and milling do not vary to a great extent in the different districts. Mining by the open-cut method costs from 12 to 30c., U. S. Cy., per ton; milling, from 45 to 80c.; other charges bring the costs up to \$1.25 to \$2 per ton, depending largely upon the size of the plant. Cyaniding of the sand costs from \$1.10 to \$2 per ton. A two 5-ft. Huntington-mill plant, operated by steam-power, can be installed in most places for an expenditure of \$20,000; the accessibility of the mine affects the figure to a great extent. A cyanide plant to treat 80 tons of sand per day would cost in the neighborhood of \$60,000 for a simple leaching equipment for sand, and no facilities for treating slime. This figure would not include any grinding machinery.

The rivers rising in the foot-hills of the eastern mountain chains of the country flow eastward into the Caribbean. They are navigable for the lower 60 miles by any vessel that can cross the bars at their mouths, where usually there are not more than 4 or 5 ft. of water. The Escondido and Wanks rivers are

navigated by river steamers; the whole of the Principulea and Banbana and the upper waters of the Wanks, Wasspue, and Pis-Pis are only navigable by native dugout canoes or pit-pans, the largest of which carry cargoes of 13,000 lb. At the head-waters, near the end of canoe navigation, rapids are found in the rivers, but covered usually with enough water to permit the pit-pans being hauled over. Some of the mines have to pack their freight by bull-teams for several miles. In the rainy season the rivers are subject to inundations often rising 40 ft. in a few hours.

Fruit steamers ply between New Orleans and Blue-

opened by the concessionaires, although some of the concessions have been in effect for several years. Early in 1908 a grant was conceded by the Government covering an area 2½ kilometres on each side of the Siuna and Matis rivers and the Banbana river from its junction with the Bana Cruz, the grant including the tributaries of all these streams as far as the head-waters. Before the concession was made there were many prospectors in the field, but for the last year practically no search for new mineral locations has been carried on. The mining laws of the country are liberal, and would attract prospectors if concessions had not been granted excluding prospectors from the best part of the field.

All the mines so far have been opened by people of small means, who increased their scale of operations out of the profits of exploitation in a small way. The country is extensively mineralized, the ores being of low medium grade as a rule, ranging between the averages of \$4 and \$10 per ton, and no bonanzas have been found. A few placer deposits have been discovered, but have never been worked except by crude methods and spasmodically.

In parts of the country not included in the concession, or land denounced before the concession went into effect, very good prospects, with extensive *manta* deposits, sufficient to warrant opening on a small scale, and

Walpatara Rapids, Banbana River.

fields and Cape Gracias á Dios. Freight for Principulea is carried up the coast in small gasoline schooners. The freight from New Orleans to the mines varies between 4 and 8c., U. S. Cy., per pound, the higher rate representing the cost at mines where hauling by bulls has to be resorted to. No import duties are collected for mining machinery; all food-stuffs for the mines, except those granted under concessions, are subject to a high import tariff. Typical rates of duty are as follows:

| | U. S. Cy. |
|-------------------------|-----------|
| Flour, per bbl. | \$1.45 |
| Beans, per 100 lb. | 0.95 |
| Rice, per 100 lb. | 1.18 |
| Lard, per 125 lb. | 9.40 |

Other duties are collected at a much higher proportional rate. There is an export duty on gold at the rate of 50c., U. S. Cy., per fine ounce of metal, payable in Government bonds under a penalty of an increase of 50%. Before the miners had a chance to buy a supply, speculators cornered the entire bond issue, and sold again at an increase of very nearly 50%. The export duty is considered a hard burden by the miners, and rather unjust, as the whole business of the northern east coast is dependent upon the mining industry.

Concessions have been granted to individuals covering such articles as tobacco, liquors, and explosives. The concessionaires demand high rates for the privilege of importing such articles as the concessions cover, the amount often exceeding the first cost in the United States. On dynamite one must pay the concessionaires \$280, U. S. Cy., per ton. Several mining concessions have been granted without in a single instance a mine or prospect having been

denounced before the concession went into effect, very good prospects, with extensive *manta* deposits, sufficient to warrant opening on a small scale, and

Santa Rita Mine.

with exceptional promise of finding a fair-sized ore-body may be obtained, at prices ranging from \$1000 to \$15,000, U. S. Cy., under terms of payment which will permit of considerable exploration, opening up and erection of a small mill, for about \$25,000, and if operations be commenced at once, they permit of making the greater part of the payments for the property out of profits. There are many prospects showing a long and continuous outcrop or *manta* of ore of sufficient value and large enough extent to warrant the risk of the amount mentioned. In this way most of the mines have been opened that are now being profitably worked. There have been some failures, but not many, and in most instances failures resulted in attempting to exploit prospects which held forth not one iota of promise

from the start. Those who will neither take too optimistic nor pessimistic a view, who can estimate the probable worth of an undeveloped deposit, and will risk a comparatively small sum, will be the ones to open up the country.

There are no actual ore reserves in any of the mines, and a field for investment of large capital would be restricted to buying up those mines which have been profitably producing for the past four or five years. While, strictly speaking, these mines are undeveloped, still the work that has been done is sufficient to reveal the nature of the deposit, allow an appropriate valuation of the ore being made, and a reasonable estimate of the probable future life.

Could several of the larger properties be combined under one management, with a staff of capable engineers, with capital enough to enlarge mills, permit clearing the rivers and improving transportation, the profits from many properties could be greatly increased, and certain of them now barely paying expenses might be made to yield handsome returns. Many small properties have not been profitable simply because the owners could not afford to carry a sufficient supply of repair parts for the machinery, and break-downs caused delays, permitting expenses to run up beyond hope of recovery before their mills could start again.

The climate is typical of tropical low-lands. The land is poorly drained, covered with a dense tropical forest, and infested with malarial fever. The more pernicious tropical diseases, such as yellow fever, bubonic plague, berri-berri, and the like, are unknown. The rainy season lasts from the middle of May to the end of November, during which time the greater part of the 130 inches of average annual rainfall occurs.

CLARENCE CARLETON SEMPLE.

Bluefields, Nicaragua, May 25.

Platoro, Colorado.

The Editor:

Sir—There is a mineral district in Rio Grande and Conejos counties, in southern Colorado, which produced large quantities of gold and silver when the mines were in operation a few years ago, both from the milling of surface ores carrying free gold, and the shipping of high-grade refractory ores. Owing to gross mismanagement and the base character of the low-grade ores in depth, together with the great expense of operation, they were closed until improved methods of milling, better means of transportation and cheaper power would enable them to be operated at a profit once more. This district extends from Summitville on the north to Platoro on the south, a distance of seven miles, and about five miles in width. The lowest formation exposed is a massive diorite, cut by later parallel dikes of similar character, carrying large quartz fissure-veins, containing gold and silver—besides sulphides in the southern part of the district. The northern portion is capped with a later flow of rhyolite, carrying large quantities of iron sulphide, containing little gold and silver. This capping has been penetrated by the dikes in the underlying diorite formation, notably at South mountain, Summitville, where a large quan-

tity of 'free gold' was milled from the surface ores. Lower levels show a refractory, low-grade, sulphide ore, which can only be treated at a profit by modern milling methods, combined with other economies. An idea of the possibilities of this district may be had from the following instance, coming under my own observation.

One of the developed properties in Platoro was thoroughly sampled by a well known mining engineer. His report showed that a tunnel driven on the vein, about 1500 ft. long, with drifts, stopes, raises, and winzes at various points, showed the vein to vary from 20 to 30 ft. wide, giving average assay values of over \$11 per ton in gold and silver. The ore when tested by a reliable firm in Denver, Colorado, with an improved cyanide process, gave an extraction of 85%, at an estimated expense of \$2 to \$3 per ton for milling at the mine; the exact cost depending upon the size of the plant installed. Mining expenses of \$2 per ton in this case would ensure a profit of \$4 to \$5 per ton. Negotiations are now pending on this property. There are a number of other properties in the district showing bodies of ore containing from \$7 per ton up. A company is now making preliminary arrangements for the installation of a large hydro-electric power-plant, on the Conejos river, only 12 miles below Platoro. This will generate sufficient power to supply the mines and mills in the camp, as well as operating an electric line from some point on the D. & R. G. railway in the San Luis valley, to the camp, a distance of 40 miles. It is estimated that from having an electric railway for transportation, and electric power for mining and milling operations, there will be a saving of at least one dollar per ton upon every ton of ore handled. This will enable operators to mine and mill \$7 ore at a profit.

Platoro, Colorado, July 20.

CHAS. S. BARNES.

Petroleum production in 1908 increased rather as a result of activity in the three great fields—California, Oklahoma, and Illinois—than the discovery of any considerable new fields. The principal new field to gain prominence was the Caddo pool, in northwestern Louisiana. The hoped for increase in production from the Markham and Goose Creek fields in Texas did not materialize, and the total from that State showed a decline in spite of the increased production in the Humble pool. In the Appalachian field 7115 new wells were drilled, of which 5292 were producers, with a total initial production of 55,002 bbl.; in the Lima-Indiana region 1250 new wells were drilled, of which 1088 were producers; in the new Illinois field 3574 wells were drilled, of which 3019 were producers, with an average initial production of 26 bbl. per well. In the Mid-Continent field 3490 wells were drilled, of which 2587 were producers of oil, 471 were producers of gas, and 432 were dry; the initial production of the producing wells averaged 83.7 bbl. In the Gulf field only 819 new wells were drilled, 606 being producers and showing an initial production of 297 bbl. In California 617 wells were drilled, of which 594 were productive, and in other parts of the country 44 wells were drilled, yielding 24 new producers.

YAMPA SMELTER, BINGHAM, UTAH.

Written for the MINING AND SCIENTIFIC PRESS
By LEROY A. PALMER.

The Yampa smelter affords a typical example of modern copper smelting practice, containing, as it does, all of the appliances necessary for the conversion of crude ore into blister copper ready for the refinery. It is a plant of 1000 to 1200 tons daily capacity situated in Bingham Canyon, Utah, about a mile and a half from the mine, with which it is connected by a Bleichert aerial tramway. The canyon is narrow for its entire length, and the site chosen on the side of the mountain possesses some disadvantages, but as these could be obviated only by going some distance into the valley, and thereby sacrificing the advantages gained by proximity to the mine, besides subjecting the plant to the danger of

as follows: it is loaded into 3500-lb. cars, which are hauled by motors to the top floor of the roaster building, and charged into the McDougall roasters. The McDougall building, as are the others, is of structural steel, with corrugated iron-sheathing. It is built in three floors to afford ready access to the various parts of the furnaces, of which there are nine. Each furnace is 18 ft. diam., with six hearths, and two arms to each hearth, each arm making a complete revolution in 56 seconds. The ore is dumped into hoppers, from which it feeds into the furnace, the arms spread it out and scrape it over the hearth, finally discharging it over the edge to the hearth beneath, where the process is repeated with the ore working toward the centre. In this way the charge is slowly scraped over the six decks, being constantly rabbled, and exposed to the action of the heat until the sulphur-content is reduced from 30 to

Yampa Smelter.

adverse litigation because of farmers, the canyon-site was decided upon as the better. All things considered, the plant as laid out is as convenient for economical operation as well could be.

The ore is received over the aerial tramway in 1500-lb. buckets, and dumped into the bins by hand, every tenth bucket being dumped to the sample bin. The ore to be sampled is discharged to a 10 by 20-in. Blake crusher, elevated and passed through a 5-in. trommel, the oversize going to a set of 14 by 28-in. Cornish rolls. The undersize from the trommel is elevated, each twentieth bucket being dumped separately, and a one-tenth cut taken from it by a Vezin sampler. This sampling is carried on only on the night shift. On the day shift the ore is fed to a 3 by 8-ft. trommel of heavy plate, with 1-in. punched holes, on a frame of four 6-in. angle-irons. The oversize is run to its bin by an inclined conveyor, and the undersize elevated and passed through the 5/8-in. trommel, the oversize going to the bin with the coarse and the undersize to a separate bin.

The progress of the fine ore through the plant is

about 5%. Coal is used in starting the furnaces, but once started, the sulphur in the ore supplies sufficient heat for the operation. Each McDougall furnace is supplied with two 30-in. elbows, which discharge the fume to the dust-chamber. This is of brick, 20 by 32 ft. 8 in. by 60 ft., terminating in a brick stack 120 by 10 ft. Brick baffle-walls are provided to check the current of the gases and allow them to deposit the dust, which falls into square steel hoppers. Cars are run beneath these hoppers and the dust loaded into them for treatment in the reverberatory furnaces. The accretions which accumulate on the walls of the roasters are barred off at intervals, and trammed to a bin adjacent to the coarse-ore bins, from which they are taken to the blast-furnaces. A 20-hp. direct-current Bullock motor drives the McDougalls.

The roasted ore, or calcine, as it is called, is discharged from square hoppers at the bottom of each furnace to 7300-lb. cars, and hauled to the reverberatory furnaces in the adjoining building. These are three in number, a 17 by 45-ft. of 150 tons capacity,

and two 17 by 55-ft. of 175 tons each. The brickwork is stayed by 4-in. I-beams, tied across the top by buckstays spaced on 16-in. centres except where two doors, each 15 by 24 in., are placed in each side to allow the furnace-men to rabble the charge. The fire-boxes are 8 by 12 by 14 ft., and both ore and fuel are fed from the top through square hoppers, there being three 15-in. openings for fuel and seven 12-in. openings for the calcine. Blast for the fire-boxes is furnished by a 16-in. No. 9 Buffalo Forge Co.'s centrifugal blower, direct-connected to a 20-hp. Allis-Chalmers induction motor. No fluxes are used in the reverberatory furnaces, the slag being controlled by the roasting process, which aims to leave an amount of sulphur in the calcine which will take up a sufficient amount of iron into the matte to leave the correct proportions of silica, iron, and lime to form the proper slag. The slag is tapped from the furnace to iron launders and run to 60-ft. slag-cars, which are hauled by a General Electric locomotive to the slag-dump. All slag from the reverberatory and blast-furnaces is wasted, being sufficiently clean so that there is no object in saving the shells.

The matte is tapped into molds and cast into ingots 9 by 20 by 48 in. These ingots are broken up by hand, and re-melted in the blast-furnace before going to the converters. This is the chief disadvantage of the location of the plant in the canyon, the topography not allowing the placing of the converter-plant so that the matte can be carried hot from the reverberatories to the converters. The disadvantage, however, is not so great as would appear at first, as the matte is used in making up the blast-furnace charges in place of the slag or slag-shells which usually enter into their composition. The fume from each reverberatory passes through a chamber in which is a 300-hp. Rust water-tube boiler, using the waste heat of the furnace to generate steam at 110-lb. pressure. One of these boilers is a type B, and the others are type C. They are fed by a 7 by 4½ by 8-in. duplex Snow piston-pump, a 5 by 5½ by 8-in. duplex Smith-Vaile plunger-pump being held in reserve. An 8 by 5 by 12-in. Fairbanks-Morse pump supplies water at high pressure for fire and for operating the turbo boiler-washers. The steam from these boilers is carried direct to the engines without the use of a superheating boiler. As the dust losses from the reverberatories are very small, no dust chambers have been provided, the fume discharging from the boiler-chambers to a brick-stack 7 by 100 feet.

An average analysis of several reverberatory slags shows:

| | % |
|--------------------------------------|------|
| FeO | 38.4 |
| SiO ₂ | 39.3 |
| CaO | 4.2 |
| Al ₂ O ₃ | 4.9 |

The coarse ore which is separated from the fine by the trommels is unloaded through hand-gates to motor-drawn cars, in the same train with which the fluxes are loaded and hauled to the blast-furnaces. Having determined by experiment, backed to a large extent by experience, the slag which is best adapted to the quality of ore which is to be treated, the smelter superintendent calculates his charge by a

comparatively simple stoichiometrical operation. It is customary to allow 90% of the slag to silica, ferrous oxide, and calcium oxide, the remaining 10% being accounted for by aluminium oxide, barium oxide, manganese oxide, and such other compounds as may be present in the ore. Having determined upon the grade of matte which it is desirable to make, governed, of course, by that possible with the ore in hand, a formula for the matte of Cu₂SFeS is usually assumed, and the content of the matte computed from it. Knowing the amount of iron that must go toward the composition of the matte, that left available for forming slag is computed to ferrous oxide, and placed against the silica and lime in the charge. Knowing, then, the composition of the desired slag and the excesses or deficiencies in the ore of the constituents, the smelter-man mixes his ores so that they will present the proper proportions of the slag-forming materials.

The Yampa is at present converting a very low-grade matte, probably the lowest of any smelter in the country. Tests are being carried on at present as to whether it is advisable to increase the grade, and the management therefore does not consider it advisable to publish its analysis. For this reason I cannot at this writing give a concrete example of slag-calculation at this plant. The method described is the one in vogue. The usual slag-composition in copper-smelting practice is from 30 to 38% silica, the remainder of the 90% being ferrous oxide and calcium oxide, and at the Anaconda works, which are regarded as an advanced type of copper-smelter, it is aimed to keep the silicious content of the slag as near 36% as possible. At the Yampa it is found that excellent results are obtained from a highly silicious slag, 45 to 46% SiO₂, which is desirable, as there is a saving in limestone, and a corresponding increase in the amount of ore treated in a given time and with practically the same amount of fuel.

The Yampa ore is of quite uniform quality, and in its crude state forms an excellent smelting mixture, its composition averaging about 2% copper and 30% each of silica, iron, and sulphur. The process of making up the charges is therefore simple, and would perhaps appear crude to one accustomed to custom-plants where many lots of varying quality are treated each day. The train is drawn in front of the coarse-ore bins, beside which are the bins containing the fluxes, and a charge loaded as follows: crude ore, 4000 lb.; lime, 1400; reverberatory matte, 300; coke, 600, the fuel therefore forming 9.5% of the total charge. The standard type of side-dumping slag-cars are used for charging, and are hauled to the furnace and the contents dumped bodily through a side door with counterweights which are raised and lowered in guides. On the day shift from five to eight 'dope' charges are added, made up as above, with the addition of 3000 lb. of slag. The slag being readily fusible tends to make the mass more molten, and to prevent the forming of accretions on the walls of the furnace. These accretions, if allowed to form, must be barred off at considerable trouble, since if neglected they will increase in size, preventing the blast from reaching all portions of the charge until the furnace finally freezes. In

that case it must be shut down and bored out, an operation which sometimes entails an expense of some thousands of dollars.

The blast-furnace building contains three furnaces, as follows: one 44 by 180 in. at the tuyeres and 66 by 180 in. at the shaft, giving a ratio of shaft to tuyere area of $1\frac{1}{2}$ to 1. There are three water-jackets on each side, and one on each end. Each side has eighteen 3-in. tuyeres, spaced 10 in. apart, with siamesed tuyere-pipes, individual valves, and all metal connection to the 18-in. bustle-pipe.

The forehearth is circular, of fire-brick, 2 by 11 ft. inside. The fume discharges through a brick down-take 48 by 102 in. One furnace, 42 by 168 in. at the tuyeres, and 72 by 186 in. at the shaft, ratio of shaft to tuyere area $1\frac{3}{4}$ to 1, three jackets on each side, and one on each end, eighteen 3-in. tuyeres 9 in. apart, with a low 15-in. bustle-pipe having metal connections to the tuyeres, which are controlled by individual valves, circular brick forehearth 3 by 12 ft. inside, and 72 by 92 in. brick down-take.

One furnace 44 by 186 in. at the tuyeres and 66 by 186 in. at the shaft, having ratio of shaft to tuyere area of $1\frac{1}{2}$ to 1, six jackets on each side, and two on each end, sixteen 5-in. tuyeres with metal and canvas connections to the 18-in. bustle-pipe, the tuyeres being regulated in groups; circular brick forehearth 3 by 16 ft., and brick down-take 72 by 118 inches.

The main air-line is 40 in. diam., and delivers air to the furnaces at 32 oz. pressure. Each furnace has a daily capacity of 175 to 200 tons of ore and flux. Tapping is carried on continuously, the slag overflowing to 30-ft. slag-cars, to be hauled to the dump by electric locomotives.

As the matte accumulates it is tapped to a channel in the earthen floor, and run to the converter-building adjoining the blast-furnace building. Here in the floor are brick-lined pits 9 by 9 by 9 ft., of sufficient size to hold the 5-ton ladles in which the matte is caught. A 20-ton Morgan electric crane handles the ladles and converters. The fume from the blast-furnace discharges through the down-takes to a square brick dust-chamber with brick baffle-walls 20 by 20 by 400 ft., terminating in a steel stack 7 by 200 ft. The stack follows the slope of the hillside, except for the last 50 ft., which is vertical, and although it is not provided with a fire-brick lining, as is frequently the case, it is still in first-class condition after 5 years' use. The dust is withdrawn through 15 by 18-in. doors, spaced on 14-ft. centres, to small cars which are hauled to the top of the reverberatory building by an electric hoist, and dumped into the furnaces.

An average analysis of blast-furnace slag shows:

| | % |
|--------------------------------------|-----|
| SiO ₂ | 45 |
| FeO | 25 |
| CaO | 17 |
| Al ₂ O ₃ | 6.9 |

In the converter-building are six 84 by 126-in. Allis-Chalmers Leghorn converters, and two stands. The converters have fourteen 1-in. tuyeres, receiving blast of 15-lb. pressure per square inch. Silicious ore is used for converter-linings. It is fed from the

bin provided for it through a No. 4 Gates gyratory crusher, reducing to 1 in., thence to a 6-ft. Allis-Chalmers pug-mill with stationary spindle and revolving bottom, in which it is ground and mixed with about 20% of wet clay as a binder. The lining is tamped in by a $3\frac{1}{2}$ -in. Ingersoll-Rand piston-drill with a 4-in. flat shoe, operating under 80-lb. air-pressure. The converter slag is poured into ladles which are hoisted by the crane, and the contents returned while hot by means of an iron launder to the forehearth of the No. 1 blast-furnace. The blister copper, which is 99% pure, is cast into 300-lb. ingots, and run down a balanced gravity plane to box-cars.

The power plant of the Yampa presents an example of efficiency that is worthy of more than passing notice. In the boiler-room are four 85-hp. return-tubular boilers generating steam at 120-lb. pressure. A 7 by $4\frac{1}{2}$ by 8-in. duplex Snow piston-pump feeds these boilers, and a similar pump raises the hot feed-water to the feed-pump for the waste-heat boilers connected to the reverberatory furnaces.

In the engine-room is the following equipment: one 12 by 30-in. 110-hp. Allis-Chalmers Corliss engine, direct-connected to a Connersville blower making 130 r. p. m., with a capacity of 100 cu. ft. per revolution; one 150-hp. Bullock induction motor, belted to a Connersville blower making 140 r. p. m., with a capacity of 100 cu. ft. per revolution; one 10 by 10-in. 70-hp. Ideal slide-valve engine, belted to a Connersville blower making 165 r. p. m., with a capacity of 55 cu. ft. per revolution; one 11 by 12-in. 75-hp. Ideal slide-valve engine making 300 r. p. m., direct connected to a 440-volt direct-current generator; one 16 by 16-in. 175-hp. Skinner slide-valve engine making 250 r. p. m., direct-connected to a 440-volt direct-current generator; one 30-hp. 14 by 14 by 20-in. Rand compressor, having a capacity of 75 cu. ft. of free air per minute, compressing to 80 lb. for the blacksmith shop, tamping machine, etc.; one 250-hp. Allis-Chalmers 16 by 34 by 48-in. tandem engine, connected to duplex air-cylinders 34 by 48 in., with a capacity of 7800 cu. ft. of free air per minute, compressing to 15 lb. for the converters.

With the exception of the Skinner, these engines are all connected to a Wheeler 16-in. barometric jet-condenser, with a 5 by 12 by 8 in. dry vacuum pump, giving a vacuum of 20 in., the altitude of the plant being 7000 ft., where the mercury column registers 22.64 in. The exhaust from the Skinner engine is carried to an open feed-water heater which raises the temperature from 54 to 194°, so that at this altitude, where the boiling point is 198° F., the feed is practically boiling when it enters the boilers. This increase in temperature is equal to $4\frac{1}{2}$ lb. of steam-pressure. The coal consumption for the battery of four 85-hp. boilers, averages 325 to 350 tons per month.

Water is obtained from a shaft sunk on the property, which gives a minimum flow of 150 gal. per minute. The shaft is equipped with three pumps, two 14 by 7 by 13-in. Cameron sinkers, with a capacity of 200 gal. per minute, and a Gould 8 by 10-in. single-acting triplex, with a capacity of 260 gal. per minute. One pump working at a time raises the water to a receiving tank, which also receives the

water from the main cooling-tower. From this tank an Aldrich pump, 13 by 12-in. vertical triplex, 900 gal., belt-driven by a 75-hp. induction motor, and a Gould pump, 8 by 10-in. vertical triplex, belt-driven by a 25-hp. direct-current motor, raise the water to a 30,000-gal. tank above the plant, from which it is distributed by gravity. In reserve as auxiliaries to these pumps are a 12 by 7 by 12-in. Knowles 200-gal., a 10 by 5 by 12-in. Knowles 100-gal., and a 14 by 7 by 13-in. Cameron sinker 200-gal. The water after being used runs to a cooling-tower and passes over a $\frac{1}{4}$ -in. screen to clean it before spraying. The cooling-tower effects a reduction of about 30° F. in the temperature. The condenser-water runs from the hot-well to a second cooling-tower, from which a 6-in. two-stage Wheeler high-lift pump, of 1000 gal. capacity, driven by a 50-hp. induction-motor, raises it against a head of 70 ft. to the tank, from which it flows by gravity to the condensers. A 300-hp., 440-volt, induction-motor, direct-connected to a 220-volt direct-current generator, supplies power for the motor haulage. This power is derived from the Teluride Power Co., and to guard against serious shut-downs from accident to the steam-generator units, 300 additional horse-power are provided for, the transformer-house being equipped with six 100-hp. transformers, three oil-cooled and three water-cooled. As previously stated, the plant is convenient to the mine, and so situated as to be free from hostile litigation on account of fume. Sufficient silica is derived from its own ores, coke is shipped in from Sunnyside, about 175 miles distant, and lime-rock from Parley's Canyon, 35 miles away. In collecting the data for this article acknowledgment is due the courteous assistance rendered by C. A. Pringle, general manager, and Frank Murphy and Thomas Maslon, superintendent and master mechanic respectively of the smelter.

Free assays are made by several of the States, but attention has recently been called by the U. S. Geological Survey to the fact that it does not make analyses or assays of ores or metals for the public. Many specimens and samples are sent to the Survey with request for assay. The most that can be done in such cases is for the Survey geologists to give an off-hand opinion based on a simple examination of the specimen; but if an assay is desired the proper course is to employ a private assayer or to send the specimen to one of the Government assay offices, where a regular charge is made for such work. Government assay offices are situated at Carson, Nev.; Seattle, Wash.; Boise, Idaho; Helena, Mont.; Deadwood, S. Dak.; Salt Lake City, Utah; St. Louis, Mo.; Charlotte, N. C.; and New York, N. Y.

West Virginia more than any other coal-producing State depends on market conditions outside of her own borders for the disposition of her coal product. The manufacturing industries of the State are comparatively unimportant when considered in connection with the large and cheap supply of high-grade fuel. Probably more than half of West Virginia's coal is shipped away to support manufacturing industries in other States.

INNOKO ALASKA DISTRICT.

Since the discovery of placer gold in paying quantities on the headwaters of Innoko river, a tributary of the Yukon, in 1906, that part of Alaska has received more attention from prospectors looking for new fields than any other district in the Yukon valley. During the last three years probably 1500 men have visited the Innoko country. A paper on this district by A. G. Maddren appears in the U. S. Geological Survey's Bulletin 379. A more detailed report is in preparation and will be issued later as a separate bulletin.

According to Mr. Maddren, the Innoko is about 500 miles long, and drains an extensive, moderately mountainous area between the Kaiyuh and Kuskokwim mountains, which separate it from the two largest rivers in Alaska, the Yukon and the Kuskokwim, on the northwest and southeast, respectively. The placer diggings are accessible in summer by way of these two rivers, the Kuskokwim route being considered by Mr. Maddren the better, as it involves but one transfer of freight. This route, however, requires an overland haul of 35 miles from the forks of the Takotna, a tributary of the Kuskokwim, to Ophir, on the Innoko. The winter routes to the valley are much shorter, as its lower portion is then frozen over.

Gold occurs in the Innoko county in placer deposits, and possibly in lodes, though so far the only production has been derived from the placers. These are all comparatively shallow—not more than 35 ft. in depth—and are in large part frozen. Most of the work already done on them may be classed as a mere prospecting of the ground. The area of economic importance lies near the headwaters of the Innoko, in a region of low mountains, and paying quantities of placer gold have been found on Ganes, Little, and Ophir creeks, all tributaries of the main river. The gold occurs in the present stream gravels and in bench gravels averaging about 60 ft. above the streams. Ganes creek is a large stream with ample water for hydraulicking, though the grade is such that the tailing would have to be elevated or disposed of by some mechanical means. The other two streams are smaller and there is some doubt whether they contain enough pay gravel to justify the expense of bringing water for hydraulicking from a distance. However, a comprehensive scheme of hydraulic mining seems to promise most for working the deposits of this district with the greatest possible profit. Such a scheme would involve thorough prospecting of all the gold-bearing ground under expert supervision, the bringing of water from a considerable distance, and the consolidating of all property interests. That the last item would be a considerable undertaking is indicated by the fact that about 1200 placer mining claims have been recorded in the Innoko district.

The total gold production of the district for 1907-8 is estimated at \$85,200, of which the season of 1908 is credited with \$72,100. Four claims have produced more than \$10,000 each in a single season, but none has reached \$20,000. The Innoko placer gold is very pure, its fineness being about 0.915.

CLASSIFICATION OF PUBLIC LANDS.

By GEORGE OTIS SMITH.

*The necessity for classifying the public land is not recent. The earliest land legislation in this country both contemplated differences in the quality and character of the public land and planned that the officers charged with their sale should be furnished with descriptions based on field examination. From 1796 down to the present day, whatever the policy that has prompted legislation with reference to public land, whether the purpose was to procure revenue, or to promote home building, or to benefit influential citizens, most of these laws recognize classes of land and presuppose classification. Yet even the honest administration of the land laws has ever been subject to criticism arising from the fact that no adequate provision was made for land classification.

A period of national awakening to the worth of the public domain appears to have followed the close of the Civil War, and in the late seventies Congress gave serious consideration to the problem of making better provision for effective administration of this great estate with its latent possibilities for national growth. We have just entered upon another epoch of realization by the nation of the true source of its wealth and prosperity, and both the legislative and the executive branches of the Federal Government are awake to the fact that exact knowledge is essential to the proper utilization of our country's great resource of land. The earlier propaganda bore fruit in the creation of a scientific bureau, first among whose functions was the classification of the public land. But this specific duty laid upon the new Federal bureau was subordinated to the more general though hardly less important task of determining the natural resources of the public domain and the opportunity for a scientific classification of the land before the larger part of the more valuable areas had passed into private ownership was lost. In the present period of aroused public opinion the land classification which leads to better use, and the field knowledge on which intelligent administration must be based, have come to be regarded as vital factors in the public land policy.

The Secretary of the Interior may be considered to be a trustee charged with the disposition of the public land, and within his department the functions of administration are divided among three bureaus: to the General Land Office belong the subdivisional surveys, the sales and the issuance of patents; to the Geological Survey has been entrusted the investigation of the resources of the public domain, with the determination of the character of the public lands, and the valuation of those whose price is not specifically fixed by law; and upon the Reclamation Service has been laid the vitally important task of insuring the full utilization of arid lands by the construction of engineering works.

The duty of classifying the unentered public lands is now definitely accepted by the United States Geo-

logical Survey, and the opportunity neglected in 1879 has for several years been vigorously improved. The Department of the Interior fully recognizes that the land laws have not been and never can be efficiently administered in the absence of a detailed and authoritative classification of the land. Thus the Geological Survey is heartily co-operating with the General Land Office to the end that the best disposition of the land may be secured, and it should be noted that no small part of the data utilized in this work represents the fruitage of the earlier general investigations of the Survey. In this present-day task of land-classification the painstaking work of the Survey geologists and engineers in the last thirty years counts for much.

Utilization is the keynote of the present public land policy, and by utilization I mean not that kind of local development that exploits the present at the expense of the future, and is promoted by the land skinner, but rather a development whose plan weighs national needs and calculates future demands, and whose accomplishment will serve our country's advance in the next century as well as in the present decade. Utilization is opposed to both non-use and waste. To withhold the land from private use, except where public use is of greater advantage to the people, is to check national progress; to dispose of the people's land for other than its highest practical use is to waste that property and to betray the trust. The public land problem thus resolves itself into, first, the determination of the best use to which the public domain can be put, and second, the disposition of the land now belonging to the nation so as to assure that use. Such a land policy needs no defense, for it is based on the safe principle of the greatest good to the greatest number.

The classification of the public lands as now carried on by the Geological Survey under the direction of the Secretary of the Interior serves two important ends, one administrative, the other legislative, and I believe both were contemplated by Congress at the time of the creation of the Survey. Not only does land classification facilitate the work of fulfilling the requirements of existing law, but the classification of the public domain and the investigation of its resources furnish Congress with the data on which to base new legislation.

A notable example of land classification in aid of proposed legislation is afforded by the Acts of March and October 1888, wherein Congress directed that an irrigation survey should be made by the Geological Survey, and further provided that the reservoir sites and irrigable lands designated as a result of that investigation should be reserved from entry, settlement, or sale pending further legislation. The legislation of 1888 was itself the logical outcome of Major J. W. Powell's 1879 report on the arid lands, and his subsequent work as Director of the Geological Survey, and the law that eventually resulted from the work thus authorized in 1888 was the Reclamation Act of 1902. As another instance where thorough knowledge of the public domain, and particularly of the character of a special tract with its strategic relation to the hydrography of the region, enabled the Department of the Interior to aid Congress may be

*Read before the National Irrigation Congress, Spokane, August 10.

cited the Act of February 20 of this year, reserving for public use eight sections of waste land in southern California. The law provides that this land shall be used for the diversion of flood-waters into underground storage, thereby replenishing the supply of underground waters in the San Bernardino valley. While apparently of only local scope the principle established in this legislation is really of great importance as providing a line of action that will be found adaptable elsewhere in securing effective conservation of waste waters. Hydrographic and topographic surveys which are in progress at the present time under instructions of the Secretary of the Interior have as their purpose the collection of information that may be presented to Congress in aid of legislation looking toward the best utilization of the water-powers on the public domain.

Land classification in aid of the administration of the public lands is now actively presecuted by the Geological Survey, and reports setting forth in detail the mineral or non-mineral character of public lands are being transmitted to the General Land Office on the coal, oil, and phosphate lands of which the Geological Survey has made actual field examination. Another line of activity is the segregation of non-irrigable lands under the terms of the Enlarged Homestead Act of February 19 of the present year. The recommendations of the Geological Survey on which the Secretary of the Interior bases his designations have not of course depended on surveys made for this specific purpose, but represent the available data collected through a period of many years by Federal geologists and engineers. The existence of this information whereby, within these few months since the enactment of the law, the Secretary has been able to designate areas in nine States and Territories, aggregating 162,000,000 acres, is in itself a forceful argument for a land classification that is complete and authoritative.

The classification and valuation of the coal land is the special phase of public land work to which the Geological Survey is giving increasing attention. Since the Executive withdrawals of 1906 the coal-fields in the public land States have been the scene of Survey activity on a scale that could not have been possible in the earlier period when the appropriations were altogether inadequate. The purpose of these classification surveys is two-fold: to expedite the complete restoration to agricultural entry of land thus determined to be non-coal although included in the general withdrawals, and to promote the utilization of the coal lands which today represent the greatest natural resource to which the people retain an unquestioned title. The geologic investigations of the last three field seasons have not only furnished a knowledge of the quantity and quality of the coal on the public domain, but have rendered possible the present policy of obtaining coal prices for coal lands. The General Land Office now depends on the Geological Survey to furnish detailed valuations for every 40-acre tract of coal that is placed on the market.

The scale on which this work is being prosecuted is indicated by the record of the two and a half months following the adoption of the revised scheme

of valuation; in this period the reports to the General Land Office released to agricultural entry approximately two and a half million acres of non-coal land in Colorado, Wyoming, and Montana, and placed selling prices on nearly 400,000 acres of coal land with an aggregate valuation of over fifteen million dollars, which is an average advance of more than 100% over the minimum prices fixed by law. Under the regulations setting forth the plan of valuation of Government coal land the price is determined on the bases of estimated tonnage, and the unit rate varies with the quality of the coal, ranging within 15 miles of a railroad. The prices thus calculated for the public coal land average less than one-tenth the usual royalty paid in the West, yet this conservative valuation will more than double the average price of public coal lands, not to mention the fact that this policy of land classification has stopped the disposal of coal lands at even less than the minimum coal price. I might cite exceptional cases like one in Wyoming where the average price based on tonnage represents a fifteen-fold increase over the old minimum price. Sales are being made at the new prices and the reports from one land office already indicate a greater activity in coal lands priced at \$25 and \$50 per acre than existed a few years ago when they sold at the minimum price of \$10 and \$20.

It is conceded that this policy of basing the price on the quantity and quality of the article sold will discourage purchase by speculators, but I maintain that the Government valuation will not impede the disposition of the coal deposits for purposes of utilization. The real development of the West will be promoted, not retarded. The situation is clearly viewed by an editor of a Western mining journal who has recently stated that this increase in valuation "can produce but one result—the lands will be sold only as they are actually needed for mining purposes. This should reduce the danger of monopoly, without promoting over-production and wasteful competition. In the end it should give future generations cheaper coal. The unearned increment will go in part to the nation rather than to individuals." If a scientific classification and adequate valuation of the coal lands will accomplish all this—protection against monopoly, over-production and wasteful competition as well as the assurance of cheaper coal to the consumer and a larger return to the public—what more can be asked?

The popular view in regard to the disposition of the public lands is in my opinion in a state of transition. Not only is the speculator now given less consideration than the entryman who desires to use the land, but by reason of the operation of the Reclamation Act, the citizens of each State are beginning to take a personal interest in the receipts of the Land Office. It is hardly necessary in this connection to bring to your attention the fact that the increased valuation of the millions of acres of public coal land must result in increased contributions to the Reclamation Fund and greater possibilities for local utilization of the agricultural lands through irrigation.

In conclusion I would mention a principle that is winning increased recognition in land legislation—

namely, relative worth. The earliest land laws provided for the reservation of mineral lands from disposal for other purposes and the present coal-land law expresses this principle of relative worth by giving gold, silver, and copper deposits priority over the coal, and the coal in turn preference over agricultural values. These distinctions necessitate land classification based on adequate field examination, and with classification data at hand the principle of relative worth can be further developed. Wherever the different values conflict the higher used should prevail. For example, the reservation or disposal of a tract of land for a dam or reservoir site should have preference over its use for agriculture. On the other hand, wherever the different values can be separated, that separation by appropriate legislation is at once the easiest and best solution of the problem, for instance, the surface rights may be separated from the right to mine underlying beds of coal. The first step in this direction was taken in March of this year in the passage of the Mondell Act for the protection of the surface rights of entrymen, whereby the home-seeker may secure all of which he makes entry, all he swears he is getting, while the coal beneath his tillable land is reserved to the nation for future disposal.

The ideal land classification would be that based on field examination, scientific and detailed enough to include every natural resource; the ideal land legislation is that which fully recognizes the principle of relative worth; and the ideal land administration is that which will assure the reservation or the disposition of the land for its highest use.

RUBY MINES OF THE MOGOK VALLEY, BURMA.

There are four principal mines in the Mogok valley, according to E. A. Wakefield, United States Consul at Rangoon. In each of these, modern tools and machinery are used. In adjacent valleys the Burmans still prosecute their searches in the old way, digging and washing by hand labor, but often with astonishing results. The byon or ruby-bearing clay is extracted by the open-quarry method. The ruby-bearing clay is dug up, carried on trolleys to the steam-mill, washed, passed through the sieves, and examined for rubies and spinels. The byon stretches almost everywhere along the Mogok valley, and wherever this clay exists rubies are to be found.

Besides the pure ruby, spinels or balas rubies are found in large quantities at Mogok. Wherever the ruby is found the spinel is sure to be present. They are both crystals of alumina, but of different shapes. While the true ruby is pure corundum only, the spinel has a minute quantity of magnesium, which lessens its hardness one-fifth. Except in a few rare cases, the expert can readily distinguish between the two. At the mines the separation of the rubies from the spinels is made by the use of the dichroscope. The stone is placed in the instrument so that a ray of light passes through it and is polarized. The true ruby shows a pure red ray, while the spinel shows a slight tinge of blue with the red. There are a few really magnificent spinels in existence, the

first among them all being the great Agincourt ruby in the English crown.

Notwithstanding the fact that the mines in the Mogok valley have produced practically all the rubies of ancient and modern times, it is difficult to learn how long these mines have been in operation, as it was always the policy of the Burmese kings to keep them as mysterious and secluded as possible, but mines were in operation for a long time previous to 1600. Mogok shows abundant evidence of prosperity. At one mine alone about 1400 tons of byon are washed daily during the busiest seasons, with resulting prosperity to the population. At the present time, as the ruby market is stagnant, there are only 800 laborers employed. When the market is active as many as 2000 workmen are required, nearly all Burmans, who are really excellent workmen in this line. The town has good roads, an excellent water supply and drainage system, and is well policed. In short, Mogok is one of the healthiest and most prosperous towns in all Burma. As the town is situated on ground which contains rubies, the mining operations are gradually encroaching on the residential and business sections. Whenever a house or street of houses is destroyed to prepare the way for mining operations, better quarters are provided for the occupants at the other end of the town. Old Mogok is a doomed place, as there are rubies everywhere within its limits, and in a comparatively short time the entire town will have been removed to the new site.

Rubies are more precious than diamonds, and are practically indestructible except by fire. While a flawless diamond of one carat may be worth roughly about \$100, a perfect ruby of the same weight would be worth at least \$200. But the increase in value as the size increases is much greater in rubies than in diamonds. A diamond of 10 carats is worth perhaps \$4000, while a ruby of that weight may be worth any price up to \$70,000, which was the value placed on a unique stone exhibited at the Franco-British Exhibition in London last year. During the present stagnation in the ruby market prices have not been reduced, but are maintained at the regular figures, even though sales are at a minimum, especially for export. In Burma itself the market for gems is surprisingly large, with a very steady demand. As the Indian places his surplus cash in gold and silver ornaments, so the Burman is inclined to invest his savings in rubies and diamonds, which may be readily realized upon in time of financial stress. In 1904-5 the exports of rubies amounted to \$273,000, in 1905-6 to \$265,000, in 1906-7 to \$327,000, and in 1907-8 to only a little more than \$2000.

Chromite occurs in deposits of commercial importance in Pennsylvania, Maryland, North Carolina, Wyoming, and California, but almost the entire production has come from California, where the largest deposits occur in Shasta and San Luis Obispo counties. The Shasta county deposits are the only ones at present operated, the principal occurrences being on Shotgun creek, one mile from the Southern Pacific railroad, in the western part of the county. The ore occurs in lenticular beds, and carries about 44% of chromic oxide.

MINING IN OAXACA, MEXICO.

Written for the MINING AND SCIENTIFIC PRESS

By E. M. LAWTON.

It is generally admitted by mining men who are informed on Mexican mining possibilities that the two States directly to the southwest of Mexico City, namely, Oaxaca and Guerrero, are as rich in mineral resources, as any other section of the Mexican Republic. The State of Guerrero, however, is a country truly 'set up on edge', with its box-canyons and extremely rugged mountains, so that transportation difficulties detract much from its position as a mining region, though it is probably rich in minerals beyond the conception of those who are best informed.

The State of Oaxaca is much more fortunate in facilities for travel and transportation. Until the advent of the Mexican Southern railroad, some ten years ago, the city and mining camps of Oaxaca were distant many days' horseback ride from Puebla, the nearest railroad point, or had a 200-mile pack-haul to Vera Cruz, which was the port to which the early mining companies had to send their rich ores or bullion for shipment to England. So truly were the people of Oaxaca cut off from the outside world that the language spoken here today is noticeable for its colloquialisms or 'patois', differing enough from the Spanish of other parts of the Republic so that a Oaxaquenean may be known by his speech. In spite of its isolation, however, the early records of the pioneer companies make a wonderful showing of metals produced, all done by the crudest methods. A number of old *Haciendas de Beneficio* are still standing, inert and deserted, with the old wooden stamps and wooden overshot wheel fast falling into decay, monuments to the sturdy character of the early English and German pioneers.

The mineral zone of Oaxaca is principally embraced in a circle with a radius of about 50 miles, having the city of Oaxaca as the centre. The principal districts are those of Ejutla, Taviche, Ocotlán, Sierra Juarez, Magdalena, and Penoles. These are generally known locally by slightly different names. Others, a little more distant, not shown on the map, are El Parién, Totolapám, and Teojomulco.

The conditions in 1907 were such that the mines in general were over-capitalized and under-developed. Owners of mines and prospects alike had an exaggerated idea of the value of their properties, and many groups of claims of doubtful value were taken up, the general idea being that anything would furnish bait for the inexperienced investor. Needless to say, today the conditions are changed. Good prospects can be purchased or bonded for from one-half to one-tenth of their former estimated value, and many doubtful ones have reverted to the Government, for lack of funds with which to pay the taxes, or because so many really promising prospects, already titled, can be had for low figures. With the gradual return of prosperity, it is easy to see that a more conservative basis will exist for the new order of things. Heretofore there has been much talk of projected railroads. Now the Mexican Southern railroad has Oaxaca for its southern ter-

minus. It is an English corporation, accredited with the necessary backing. The company has lately purchased outright several embryo 'through lines', originally projected to the nearby camps, or to the coast, east and west, and the local street-car lines as well. The uncompleted road to Taviche, for instance, has been revived, and is under construction, so that trains will soon be running to that point. One of the desirable features of this development is that the local smelter company, now re-organized and making necessary preparations for an early start, is dependent first of all on the Taviche ores to furnish product for treatment.

In order to connect with the Taviche road at Ocotlán, the Mexican Southern also acquired the Oaxaca & Agrícola road running to a point beyond Zimitlán. The concession for this road extends to a point considerably farther south, and either that route or the Oaxaca & Orient, also bought by the Southern, and already operating as a tram-line some miles outside of the city, will be utilized for a through line to the coast or to connect with the Tehuantepec National, as soon as the necessity fully warrants the expenditure. Other railroad projects are spoken of as possibilities, notably that of the St. Louis Iron & Steel Co., which has for over two years been making surveys and preparations to connect Oaxaca with their extensive iron mines in Santiago Minas district on the Rio Verde.

There are, by actual count, over 150 American mining companies or individuals operating or owning separate properties in the nearby camps. These represent an actual investment, as near as can be estimated of \$10,000,000 U. S. currency. Nor does this include the English or other foreign enterprises whose capital makes up a very decent additional figure. Of late much interest has been awakened in the coal and oil prospects of the outlying districts. The Oaxaca Iron & Coal Co., of which the A. B. Adams Co. of Mexico City is the actual head, has had an extensive corps of American engineers in the vicinity of Tlaxiaco during the past year or more, absolutely proving the coal-beds of that region. This concern is projecting a railroad from Puebla by way of the property and then directly south to the Pacific. Veins as large as 20 ft. wide have been found, and examinations have been made by some of the eminent geologists of the United States.

Recently Usher Carson, of Kansas City and Oklahoma, in an interview, has acknowledged the leasing of a tract of some 50,000 acres, near the town of Jamiltepec, in this State, to the south of the city of Oaxaca, for oil purposes. Mr. Carson, from his operations in the Oklahoma fields, is no doubt fully justified in believing the oil lands of this State worthy of development. Returning to the real mining matters, however, the natural inquiry is, what showing is being made for the large amount of money invested? At the present time there are 18 mills actually erected within the confines of Oaxaca. Of these many have been installed, as is too often the case in new camps, before the mines had been sufficiently developed to warrant a treatment plant. The majority of these mills have been built for amalgamation and concentration only. Some of the most

successful have not been averaging a recovery of more than 50% of the assay value of the ore, and the tailing has muddied the streams for many miles below the plant. A few have cyanide equipment, and in some cases these have never been used. But in the new régime a marked difference exists, in that these same companies are seeking expert technical and practical men, who can and will see that such appliances are installed as will yield high percentage of recovery.

There are building at this time two or three mills, all combining the latest features of cyanide treatment. Four additional plants are either asking for bids, or have let contracts for construction. A custom mill of 100 tons daily capacity is in process of erection, though the work has been stopped for the present in order to secure tests by competent engineers as to the best treatment, which information was not secured in the earlier plans of the company. So, in all, there are more than 20 mills either built

Casa Blanca Escuadra Mine.

or soon to be completed, of from 10 to 100 tons daily capacity. No mention is made of numerous other companies contemplating the erection of plants, most of whom have their properties already developed up to a point that will justify such action.

Much has been said about the quality of the labor to be had in Mexico for mine operations. It is well known that the average mine laborer in Mexico, be he *peon* or *barretero* (common laborer or driller), is more or less an erratic individual. He usually has a strong penchant for holidays, religious or others; he too often likes his *mescal* or *aguardiente*. But there are many virtues about the mine laborer in Mexico. The question of an 8-hour day does not bother him. More often he will work 10 or 12 hours, utilizing time between blasts for his *tortillas* and *frijoles*. Work is mostly done under a contract system, where the contractor himself makes a hand, and sees to it that his assistants 'put in their best licks'. The writer has contracts running at the present time for tunnel-work in hard rock for \$18 per lineal metre. This, of course, includes all expenses other than managerial. The cost-sheet for the San Francisco mine in the Taviche district, where the working face is at present 275 metres from the tunnel-mouth, shows a total direct cost of \$22.30 per metre of advance. H. S. Denny, of the firm of Denny Bros., well known for their work in South Africa, in a

recent interview thus speaks of the mining industry in Mexico: "In considering the possibilities of the mining industry in Mexico, I can only say that I am pleased with the result of the observations thus far made. Whether we judge the country from the standpoint of its mineral distribution or from the variety of minerals to be found here, or from the richness of the ore deposits, or from the natural working facilities, Mexico can claim equality with any mining country of the world. From Sonora and Chihuahua on the north to Guerrero on the south, and from Vera Cruz on the east to Jalisco on the west, there exist records of mineral production of such variety and magnitude that no more eloquent testimony is needed to carry conviction to the mind of anyone interested. Then, too, it must be considered that the work thus far done has been accomplished in the face of great disadvantages, and with the absence of modern mining methods, hence it seems reasonable to assume that under improved con-

San Jose de Gracia Mine.

ditions the possibilities of the mining industry in this country will be enormous."

Platinum exports from Colombia in recent years are estimated as below by Viconte Parra R., director of the Bureau of Statistics, of Bogotá, who says that discrepancy in value may be explained by the fact that shippers do not always give the market prices in the invoices.

| Whither exported | Quantity lb. | | | Value | | |
|---------------------|-----------------|-------|-------|----------|-----------|---------|
| | 1905. | 1906. | 1907. | 1905. | 1906. | 1907. |
| United States .. | 300.4 | 326.5 | 20.5 | \$26,810 | \$74,815 | \$2,856 |
| Germany | 8.8 | | | 800 | | |
| France | 1,954.2 | 212.5 | ... | 52,429 | 42,744 | |
| United Kingdom | 211.7 | 26.8 | ... | 3,049 | 4,660 | |
| Total | 2,475.1 | 565.8 | 20.5 | \$83,088 | \$122,219 | \$2,856 |

There is great difficulty in making any forecasts of the probable future output of platinum from Colombia, not because the country is unexplored and unknown, as many reports state, for in the days of the Spanish régime the Chocó was thoroughly exploited for gold, and in recent times every stream has been visited wherever a canoe could be paddled. All the platinum-bearing rivers are known, and the position of the alluvial deposits fairly well ascertained. The difficulty arises from the fact that no organized or scientific attempt has yet been made to test the platinumiferous capabilities of the several districts

PLATINUM AND GOLD LOSSES IN DREDGING.

Written for the MINING AND SCIENTIFIC PRESS
By W. B. WINSTON.

Some time ago W. H. James, of the Vilorio Syndicate, Ltd., Oroville, California, made some tests to determine the amount of platinum in the gravel and the losses in platinum and gold from the tables of a Bucyrus 5-ft. dredge. To determine the amount of platinum in a certain area to be dredged a shaft was sunk and the gravel passed over a rocker to recover the gold content and to concentrate the heavy sand with which the platinum is mixed. The concentrate thus produced is shown as sample 'A' under date of June 10. A test of the tailing behind the dredge to determine the gold and platinum losses is tabulated as sample 'B' under date of June 14. This sample was obtained by uniformly sinking small pits to accessible depths at regular intervals over the exposed sand-area behind the dredge. The weight of this sample was 1800 lb., and as it is estimated that one-third of the total material passes through the 5/16-in. perforations in the screen-plates, this would represent 1.42 cu. yd., based on the weight of 3800 lb. of gravel per cu. yd. as previously determined. At the time this sample was taken the dredge was digging within 50 ft. of the shaft which produced sample 'A' concentrate. The total 'A' and 'B' concentrate was sent to A. A. Hanks, of San Francisco, for gold and platinum determinations, with the result as shown in the table below.

| | June 10. | June 14. |
|---|----------------|----------|
| | No. of sample. | |
| | A. | B. |
| Material handled, cu. yd..... | 8.2 | 1.42 |
| Weight of concentrate, lb..... | 9 | 1 1/4 |
| No. cu. yd. to one ton concentrate.... | 18.22 | 22.40 |
| Concentrate per month, tons..... | 37 | 30 |
| Value of concentrate per 2000 lb., gold. | trace | \$4.95 |
| Value of concentrate per 2000 lb., platinum at \$40 per oz..... | \$6.40 | \$8.80 |
| Losses per cu. yd., gold..... | trace | \$0.22 |
| Losses per cu. yd., platinum..... | \$0.35 | \$0.39 |

Comparing the result of the samples 'A' and 'B' the value per cubic yard of each in platinum compares favorably. The gold result of sample 'A' shows that only a trace of gold escaped from the rocker into the concentrate, while in sample 'B' the loss in gold from the dredge-table was only 0.22c. per cubic yard, or less than 2% of the value actually recovered during the test period.

A summary of sample 'B' would be as follows: approximate loss of concentrate per month in tons of 2000 lb., 30 tons; value of the concentrate per month in gold, \$148.50; value of the concentrate per month in platinum at \$40 per oz., \$264; total loss per month with platinum at \$40 per oz., \$412.50; total loss per month with platinum at \$20 per oz., \$280.50.

In order to recover the above concentrate, after the installation of suitable concentrators or jigs, which would cost approximately \$7000, it was estimated that additional labor and power would be necessary to care for the machines and product as follows: Two men at \$3 per day, or \$180 per month; 10 hp. to run the machines at \$6 per hp., or \$60 per month; making a total monthly cost, not including in-

cidental delays and repairs to the machine, of \$240. This monthly cost of \$240 would give a product of approximately 30 tons of concentrate at the dredge ready to be shipped for treatment and \$172.50 would be the available surplus to meet all subsequent charges and profit. This assumes the platinum to bring \$40 per oz., which is excessive. If the platinum sold at \$20 per oz. the surplus of \$172.50 would be reduced to \$40.50. The average price received for platinum from the Oroville district is from \$17 to \$20 per ounce. The proportion of platinum saved in dredging operations does not exceed 10% of the recovery.

Iron ore deposits in Brazil, according to George E. Anderson, Consul-General of the United States at Rio de Janeiro, are larger than currently estimated. The Brazilian Government has just transmitted a report, for the use of the International Geological Congress, which meets next year at Stockholm, containing the results of a survey sent out for the purpose of studying the deposits. Although the text of this report is withheld, pending the use to be made thereof by the authorities for whom it was prepared, enough has been made public to predict that it will startle the iron world and be the sensation of the Congress. The examination of the deposits in Minas Geraes discovered 52 outcroppings of ore which was from 60 to 75% pure iron, free from all impurities which might interfere with its proper smelting. Of these outcroppings the expert selected 9, of average size and quality, which he carefully surveyed and measured, calculating their contents at a little less than 1,000,000,000 tons of very high-grade ore, on or near the surface, and in situations permitting easy working and economical handling. On the basis of the surveys made, the 52 deposits contain a little less than 6,000,000,000 tons of the highest-grade ore. In addition, loose high-grade ore was found to an amount as large as that found in the outcrops, the total high-grade ore found thus amounting to 12,000,000,000 tons. As Brazil, for various reasons, will be unable to work these vast deposits, they have recently been visited by representatives of American and British syndicates, with a view to making contracts for ore shipments, in the immediate future, from Rio de Janeiro or from Victoria, about 300 miles north of Rio de Janeiro. The only result of these visits, as far as known, is the completion of a contract between a party of one of the British syndicates and the Victoria & Diamantina Railway Co. for ore shipments by way of Victoria.

Alabama is peculiarly favored in its ability to manufacture cheap iron, although the ores are not of so high a grade as those from Lake Superior, which feed the furnaces of the Northern States. Alabama's proportion of iron production is usually larger in years of depression than in flush times. This is illustrated by the statistics of pig-iron production in 1908, which show that Alabama's output was 17% less than in 1907, while in Illinois the percentage of decrease was 31; in Virginia, 33; in Pennsylvania, 38; in Ohio, 45; in Maryland and West Virginia, 65; and the average for the entire United States, 38.2.

COMPANY REPORTS.

CALUMET & HECLA.

The annual report of the Calumet & Hecla Mining Co. for the year ended April 30 is issued. Comparison of the balance sheet for four years is as follows:

| | | | | |
|---------------------------------|--------------|-------------|-------------|--------------|
| Assets: | 1909. | 1908. | 1907. | 1906. |
| Cash and copper.. | \$6,384,305* | \$4,685,422 | \$6,477,190 | \$7,953,251 |
| Notes, bills receivable | 406,000 | 650,017 | 1,281,768 | 1,140,121 |
| Insurance fund .. | 967,919 | 959,724 | 953,340 | 995,764 |
| Development and equipment fund. | 15,882 | 554 | 45,145 | 1,827,544 |
| Total | \$7,774,106 | \$6,295,719 | \$8,757,444 | \$11,916,691 |
| Liabilities: | | | | |
| Notes and bills payable | \$ 848,112 | \$1,337,737 | \$1,228,502 | \$ 408,862 |
| Drafts in transit. | 104,226 | | | |
| Machinery contracted | | | | 878,000 |
| Note Keweenaw Association | | 250,000 | 500,000 | |
| Employees' Aid Fund | | 7,017 | | |
| Total | \$ 952,338 | \$1,594,754 | \$1,728,502 | \$1,286,862 |
| Surplus | 6,821,768 | 4,700,964 | 7,028,942 | 10,629,819 |

*Copper taken at 13c., mineral at 7c.
Notes outstanding amounting to \$8,519,000 are as follows:

| Amount. | Rate, Percent. | Dated. | Maturity. |
|-------------|----------------|-------------------|-----------|
| \$1,700,000 | 5 | March 1, 1909 | 3 years |
| 1,000,000 | 5 | March 1, 1909 | 10 years |
| 1,685,000 | 5 | February 18, 1909 | 10 years |
| 4,134,000 | 4 | February 18, 1909 | 10 years |

The refined copper product of the company for recent years ending April 30 has been as follows (in pounds):

| | | | |
|-----------|------------|-----------|-------------|
| 1900..... | 98,624,789 | 1905..... | 85,644,401 |
| 1901..... | 72,653,332 | 1906..... | 101,031,799 |
| 1902..... | 79,964,066 | 1907..... | 93,898,963 |
| 1903..... | 76,632,912 | 1908..... | 78,980,000 |
| 1904..... | 76,620,145 | 1909..... | 82,816,230 |

The holdings of Calumet & Hecla in its subsidiary companies on April 30, 1909, compare with its holdings a year ago as follows:

| | Shares issued. | Owned by C. & H. Apr.30,'09. | Owned by C. & H. Apr.30,'08. |
|---------------------------|----------------|------------------------------|------------------------------|
| Allouez Mining Co..... | 100,000 | 42,978 | 42,978 |
| Centennial Con. Min. Co.. | 90,000 | 46,080 | 46,080 |
| Frontenac Copper Co..... | 20,000 | 20,000 | 20,000 |
| Gratiot Mining Co. | 100,000 | 50,100 | 50,100 |
| La Salle Copper Co..... | 302,977 | 160,050 | 160,050 |
| Manitou Mining Co..... | 20,000 | 18,000 | 18,000 |
| Osceola Con. Mining Co.. | 96,150 | 32,781 | 22,671 |
| Superior Copper Co. | 100,000 | 50,100 | 50,100 |
| Dana Copper Co. | 40,000 | 36,500 | 36,400 |
| St. Louis Copper Co..... | 40,000 | 35,450 | 35,450 |
| Laurium Mining Co. | 40,000 | 26,900 | 1,900 |
| Seneca Mining Co. | 20,000 | 11,207 | 891 |
| Isle Royale | 150,000 | 27,500 | |
| Ahmeek | 50,000 | 24,796 | |
| Tamarack | 60,000 | 19,400 | |

President Agassiz says in part: During the past year the company produced mineral equal to 81,178,326 lb. of refined copper, against 86,528,009 lb. last year. The product of refined copper was 82,816,230 lb. In the year ending April 30, 1908, the product of refined copper was 78,980,466 lb. We have continued to take out the shaft-pillars of Hecla No. 2 and 3, and of South Hecla No. 11. At the seventy-third level under South Hecla shaft No. 9-10 there has been a marked change for the better in the quality of the conglomerate. Should this new shoot develop in length and depth, it will give us an important addition to our stoping ground. The electric hoist for the sub-shaft in the 'five forties' has been placed in position, and is now working satisfactorily. We have continued sinking all the shafts on the Osceola amygdaloid, and in the past year have opened 23,475 ft. of drifts, as compared to 19,820 ft. in 1907-8. The character of the openings is satisfactory. We began the work of opening the Osceola amygdaloid May 1, 1897, and stopped it November 1, 1901. During that time

we drove 66,860 ft. and five shafts were sunk to a total depth of 5455 ft. Work was resumed July 1, 1904, and up to the present time the total length of the drifts is 127,920 ft., and the total depth of six shafts 13,480 ft. The tonnage now opened is about 15,000,000. At a depth of 5000 ft. on the slope this lode has been found to carry fair quantities of copper in the Tamarack and deeper parts of our property. The product from this lode the past year was secured largely from openings which are now so extensive that we feel justified in increasing our stoping.

On the Kearsarge lode we have continued to sink No. 21 shaft and to drive, with moderate results. The percentage of copper in the conglomerate has continued to decrease. About 35 lb. is now saved per ton of rock. We stamped 1,952,541 tons of conglomerate, as compared to 1,894,176 tons in 1907-8. We stamped 747,378 tons of amygdaloid rock from the Osceola lode, yielding 12,722,226 lb. of copper, as against 603,891 tons, yielding 11,145,220 lb. in 1907-8. An addition has been made to the foundry, nearly doubling the floor space.

We have erected a power-line to the Lake Superior Water Works and have installed an electrically driven centrifugal pump of a capacity of 3,000,000 gal. daily, and are now sending water from these works to the mill-boilers at Torch lake. To regulate the flow a tank of a capacity of 750,000 gal. has been built near the mills. The re-grinding mill-building has been finished, and during the past year 24 of the Chilean mills have been installed; they are now running satisfactorily. We are extracting 4 lb. of copper from a ton of tailing, treated at a cost of about 5c. per lb. At present the production of the mill is about 1,000,000 lb. per year.

We are organizing the White Pine Copper Co. to develop the lands which carry the Nonesuch lode, to be conveyed to that company by the Keweenaw Association and others. We shall own about half the shares of this company at a cost of \$100,000 spent in exploration and on condition of advancing the money needed for its development. Acting under the authority given at the annual meeting of the stockholders on August 16, 1905, your directors have, at a cost of \$8,592,130, in notes and cash, purchased: 25,000 shares of Laurium Mining Co., 10,316 shares of Seneca Mining Co., 25,507 shares of Isle Royale Copper Co., 9600 shares of Osceola Consolidated Mining Co., 19,400 shares of Tamarack Mining Co., 24,796 shares of Ahmeek Mining Company.

Three mechanical drill sharpeners, with a capacity of 6000 drills per day, have been installed in the Calumet blacksmith shop and are working admirably. About 3400 drills per day are now being sharpened. The change of the gauge of our railroad to standard has been completed, with the exception of the tracks leading to three of the Osceola amygdaloid shafts, so that nearly all the rock is now run to the mills in large 40-ton cars fitted with modern brakes. Five locomotives have been re-modeled to standard gauge.

The production of all the mines in which the Calumet & Hecla Mining Co. holds stock is at present somewhat over 50,000,000 lb. of copper per annum. We hope that with a reasonable price for copper the returns from our holdings in the companies enumerated in the treasurer's report will, at least, be sufficient to pay the interest and the principal of the notes we have given, before the expiration of the 10 years during which they become due. The expenditures of the aid fund during the fiscal year amount to \$63,299. The value of the aid fund at cost is \$115,230.

ALASKA'S coal output for 1908, as reported to the United States Geological Survey, was 3107 tons, with a value of \$14,810, as compared with 10,139 tons in 1907, valued at \$53,000. Four mines were operated in 1907, but only three were productive in 1908. Of these, one was at Port Graham, Kenai peninsula (lignite); one at Chicnik, Alaska peninsula (bituminous); and one at Chicago creek, Seward Peninsula (lignite). In addition to the output of these mines, a few tons of coal were mined for domestic use at Tyonek, at several points on the Yukon, at Cape Lisburne, and at Wainwright inlet, in northern Alaska, where the Eskimos are utilizing a lignitic coal for fuel, in place of the fast disappearing driftwood.

Petroleum Production in 1908.

Final figures for 1908 collected by the United States Geological Survey show that the total production aggregated 179,572,479 bbl., valued at \$129,706,258, an increase in quantity of 8.11% over 1907. Oklahoma led all the States in production, with a total of 45,798,765 bbl., an increase of 5.23% over 1907; California was a close second, with 44,854,737 bbl., an increase of 22.85% over 1907; but Illinois gained the greatest percentage, rising from 24,281,973 bbl. in 1907 to 33,685,106 bbl. in 1908, a gain of 38.72. Colorado, Louisiana, Michigan, Missouri, Utah, Wyoming, and West Virginia also showed gains in production. The declines were in Indiana, where it was nearly 36%; in Kansas, 25; Ohio, 11; Texas, 9; Pennsylvania, nearly 6; New York, 4.3; and Kentucky and Tennessee, 11 per cent.

The average price of petroleum for the entire country in 1908 remained identical with that in 1907, but there were considerable variations of an important character in individual States. The most notable of these was the increase in price in California, from 37c. per bbl. in 1907 to 52¼c. in 1908. The Gulf States, Louisiana, and Texas showed a decline in value from a little over 80c. to 60c. The Appalachian oil showed a slight increase in value, from \$1.75 in 1907 to \$1.79 in 1908. On the whole, prices were remarkably steady, considering the notable increase over the large production of 1907.

In the following table are given the total quantity and value of crude petroleum produced in the United States during the years 1907 and 1908, by States:

| State. | Quantity, bbl. | Value. | Average price per bbl. |
|--------------------|-------------------|---------------|---------------------------|
| 1907. | | | |
| California | 39,748,375 | \$ 14,699,956 | \$0.370 |
| Colorado | 331,851 | 272,813 | 0.822 |
| Illinois | 24,281,973 | 16,432,947 | 0.677 |
| Indiana | 5,128,037 | 4,536,930 | 0.885 |
| Kansas | 2,409,521 | 965,134 | 0.401 |
| Kentucky | 320,844 | 862,396 | 1.051 |
| Tennessee | | | |
| Louisiana | 5,000,221 | 4,063,033 | 0.813 |
| Michigan | 4,000 | 6,500 | 1.625 |
| Missouri | | | |
| New York | 1,212,300 | 2,127,748 | 1.755 |
| Ohio | 12,207,448 | 14,769,888 | 1.210 |
| Oklahoma | 45,798,765 | 17,513,524 | 0.402 |
| Pennsylvania | 9,999,306 | 17,579,706 | 1.758 |
| Texas | 12,322,696 | 10,401,863 | 0.844 |
| Utah | 9,339 | 21,883 | 2.343 |
| Wyoming | | | |
| West Virginia | 9,095,296 | 15,852,428 | 1.743 |
| Total | 166,095,335 | \$120,106,749 | \$0.723 |
| 1908. | | | |
| California | 44,854,737 | \$ 23,433,502 | \$0.5225 |
| Colorado | 379,653 | 346,403 | 0.913 |
| Illinois | 33,685,106 | 22,648,881 | 0.672 |
| Indiana | 3,283,629 | 3,203,883 | 0.976 |
| Kansas | 1,801,781 | 746,695 | 0.414 |
| Kentucky | 727,767 | 706,811 | 0.971 |
| Tennessee | | | |
| Louisiana | 6,835,130 | 4,131,173 | 0.604 |
| Michigan | 15,246 | 22,345 | 1.466 |
| Missouri | | | |
| New York | 1,160,128 | 2,071,533 | 1.7856 |
| Ohio | 10,858,797 | 14,178,502 | 1.306 |
| Oklahoma | 45,798,765 | 17,694,843 | 0.386 |
| Pennsylvania | 9,424,325 | 16,881,194 | 1.7912 |
| Texas | 11,206,464 | 6,700,708 | 0.598 |
| Utah | 17,775 | 27,920 | 1.57 |
| Wyoming | | | |
| West Virginia | 9,523,176 | 16,911,865 | 1.776 |
| Total | 179,572,479 | \$129,706,258 | \$0.722 |

Commercial Paragraphs.

ATKINS, KROLL & Co., Kohl Bdg., San Francisco, California, announce that they have been joined by Mr. David Atkins and Mr. E. N. Atkins, formerly of DeGolia & Atkins, the business of which firm they have taken over. In addition to handling mining supplies, pebbles, chemicals, refractories, etc., they are now handling carbons and bortz for diamond-drills, and the new department embraces the purchase of the more uncommon ores of commercial importance, such as vanadium, tungsten, antimony, etc.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE TRANSIT. Published by the College of Applied Science, State University of Iowa. Pp. 127. Ill. Iowa City, 1909.

GYP SUM AND GYP SUM PRODUCTS IN 1908. By E. F. Burchard. U. S. Geol. Survey, Adv. Chapter, Mineral Resources for 1908. Pp. 10. Washington, 1909.

PRODUCTION OF FLUORSPAR AND CRYOLITE IN 1908. By E. F. Burchard. U. S. Geol. Survey, Adv. Chapter, Mineral Resources for 1908. Pp. 16. Washington, 1909.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA. By W. H. Wallace. Pp. 13. Hobart, 1909.

Report for the quarter ending March 31, 1909.

INVESTIGATION OF THE PEAT BOGS AND PEAT INDUSTRY OF CANADA DURING 1908-9. By Erik Nyström and S. A. Anrep. Dept. Mines, Mines Branch, Bull. No. 1, pp. 25, Maps. Ottawa, 1909.

This paper includes detailed surveys of a number of the bogs, with results of drilling and analyses. The methods of preparing peat for the market are also discussed.

HISTORY OF THE CLAY-WORKING INDUSTRY IN THE UNITED STATES. By Heinrich Ries and Henry Leighton. 8vo., pp. 240, Index. John Wiley & Sons, New York, 1909. Price \$2.50

This is a portion of the economic history of the United States being prepared under the direction of the Carnegie Institution of Washington. It is the only book covering this field, and will be widely useful to students, both of ceramics and of economics.

TRANSVAAL CHAMBER OF MINES. NINETEENTH ANNUAL REPORT. 8vo., pp. 633. Johannesburg, 1909.

The report for 1908 follows the style of the earlier volumes and contains a large amount of valuable detailed information about labor, mining regulation, output, and every phase of mining on the Rand. Transvaal is to be congratulated on having so excellent a system of publicity.

INFORME SOBRE LA COSTA SUR DEL PERU. BOLETIN DEL CUERPO DE INGENIEROS DE MINAS DEL PERU, No. 70. By V. F. Marsters. Lima, Peru, 1909.

This volume of 112 pages is one of a number issued recently under the auspices of the Department of Fomento. It gives in considerable detail the geology of the Ica valley of the region east of Huayuri, of the Rio Grande, of the valley of Yauca, the surroundings of Arequipa, and the region east of Tambo, as well as other areas in the south of Perú. The volume is well gotten up, and is accompanied by many illustrations, maps, and cross-sections.

Catalogues Received.

The W. S. ROCKWELL Co. New York, in its new catalogue (No. 5) describes muffle furnaces for assaying.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY Co., Denver, Colorado, under date of August 2, has issued its regular monthly announcement.

The STROMBERG-CARLSON TELEPHONE MFG. Co., Rochester, N. Y., in Pamphlet No. 18, shows its 5-line combination switching telephone and a 2-line switching device.

The CHAIN BELT Co., Milwaukee, Wis., has just published an elaborate and handsome catalogue giving complete data regarding its line of elevating, conveying, and concrete machinery.

The A. LESCHEN & SONS ROPE Co., St. Louis, Mo., is distributing an attractive folder giving excellent views showing the progress of construction of the Cathedral of St. John the Divine at New York.

The KEUFFEL & ESSER Co., New York, has just published a folder describing the new Log Duplex Slide Rule. This ingenious device is an improvement on the ordinary slide-rule by which problems involving involution and evolution and more easily solved.

EDITORIAL.

FRiction between Mr. Gifford Pinchot and Mr. Richard A. Ballinger over the public-land policy is most embarrassing. The public is not certain how much it may grab or how much devastate; in fact, the present situation renders it quite impossible to decide on which gentleman it is wise to bestow the more deference.

Elimination of sulphuric anhydride from smelter fume by neutralization and filtering through raw-wool bags has been demonstrated to the satisfaction of Judge John A. Marshall, of the Federal Court in Utah, who has permitted the United States Smelting, Refining & Mining Company to resume the operation of its copper furnaces while this system is applied. Meanwhile the old war against the smelters in the vicinity of Redding, California, has been renewed. A Farmers' Protective Association has been organized at Olinda, and other districts are asked to join in the crusade. The so-called 'secret process' of the United States Smelting, Refining & Mining Company should be introduced at its Kennett smelter to absolve it from the condemnation of the community.

Telegraphic communication is constantly assuming greater importance in the conduct of business, despite the enormous rates which prevail in this country. These have continued practically unchanged for decades, while the cost of mail service has been decreasing. It is something of a shock to one used to the exorbitant rates for telegraphic despatches in the United States to cross the border into Mexico and find a telegraphic tariff in force that invites one to use the wire rather than write, seal, and stamp a letter. For a mere pittance messages may be sent into the wildest mountain districts, where the traffic is small and the cost of maintenance relatively high. As a means of escape from the trammels of high costs telegraphic codes have been developed to a high state of perfection, and recently the 'Miners' & Smelters' Telegraphic Code' has been elaborated for the special convenience of the mining world, supplementing the well known system of Bedford McNeill, permitting of the combination of two five-letter code-words into one. In another column we print an ingenious plan devised by Mr. Mark R. Lamb for applying the same principle to other codes. Since that was put in type an order has been issued by the sympathetic Western Union and Postal Telegraph companies, taking effect on September 1, which will require payment for two words on all code-words exceeding five letters in length when such words are not found in the English dictionaries. This ruling will provoke universal discontent, and will hasten the absorption of the telegraphic service as a function of the United States Post Office, or it will bring

about a strict regulation of these private corporations by Federal statute. The time has gone by for a corporation to embarrass communication by increasing rates rather than provide improved equipment to handle a larger volume of business on a reduced margin of profit. The mining industry is peculiarly affected by the new rates of the telegraph companies, since the mines lie chiefly in those zones where the highest tariffs apply. The question will undoubtedly receive consideration at the Mining Congress next month.

SLIME treatment is just beginning to receive scientific investigation. It is, perhaps, the most fertile field within the department of ore-milling open for study and experiment to the trained technologists of today. It has been our pleasure to advance the serious consideration of this subject, and further data will be published from time to time. This week appears among our 'Discussions' an interesting letter from Mr. Horace G. Nichols, who made an important discovery in slime-settlement which is now being practically applied. Mr. Nichols has tentatively submitted definitions of slime, considered with reference to concentration and to filtration in lixiviation processes that will undoubtedly call forth valuable comment, for no game awakens keener enthusiasm than the making of definitions. The point turns practically on the office of slime as affecting viscosity. Mr. Nichols raises the question whether "the force opposed to gravity be due more to viscosity of medium or to electro-static repulsion," affirming that "retardation of settlement clearly follows accumulation of concentration." On the other hand, we must point out that increased hydroxyl concentration retards the settlement of all negatively charged particles, at the same time decreasing the viscosity of the solution. The presence of colloids is not essential to this retardation of the settlement of negatively charged particles, but as the specific gravity of a solution is increased by dissolved colloidal substances in the sol form, settlement of suspended matter will be thereby hindered.

Protective Tariff.

Apology is poor remedy for failure to make honest downward revision of the tariff. President Taft signed the bill as the best that could be had. It is probably as good as can ever be produced under the present system. An unscientific method must perforce yield a product of disorder and injustice. The moment a tariff goes beyond the simple function of producing revenue and essays 'the encouragement of industry', it disturbs the normal balance of trade, and offers prosperity to some with corresponding hardship to others. The practical application of protection involves the promotion of certain industries, and necessarily fails to benefit all. This does not argue the principle to be wrong. The question is whether the gain is commensurate with the cost. As a cardinal point it is affirmed that no industry should be encouraged by a tariff which destroys some other. It seems wrong to take away one man's living while augmenting the riches of another. Perhaps it is wrong; but civilization is not gentle and beneficent

when it comes to the individual. It shares the icy indifference to the unit which is characteristic of biologic law. It looks to the welfare of the mass alone, prate and theorize as we may. Civilization as a process is not beautiful; it is the exterior result that awakens enthusiasm, that gives delight to those who are not ground under its merciless wheels. The tariff as constituted is in keeping with the human system of which it is but a part. It is the expression of the greed of the aggressive. It is framed for those who can fight hardest and can best use seductive persuasion to gain their ends. It does not offer a sop to the weakling; protection is for the strong, to make them stronger. Could there be a better illustration of the working of the law of the survival of the fittest? In other terms it is the survival of the successful.

But because a protective tariff is essentially a building up of something showing capacity for growth, for the assumed benefit of the people at large, no argument may be adduced from that in favor of the unscientific method employed. The spectacle of futile taking of evidence in Congressional committees regarding costs of production, the open trading of support between representatives of different districts with their corresponding interests, causes wonder that any approach to a reduction of duties may have been achieved. It is uncertain how far reduction of duties will take place by virtue of the Payne-Aldrich bill; but it is conceivable that a tariff commission could intelligently accomplish it if constituted with proper power to adjust the schedules under an established maximum. A beginning for such a reform was contemplated in the bill as originally drafted; as finally passed it grants the President power to appoint agents to "secure information to assist in the duties imposed upon him and information which will be useful to the officers of the Government in the administration of the customs laws." This is substantially the power he had possessed before for appointing special agents, but the new law enables him to appoint men of the highest talent, to continue them in service, and to pay them adequately. The President can, if he will, create a permanent body to acquire and publish information which will have an important educational value. It should reveal how adjustments to changing industrial conditions at home and abroad may be effected by a sliding scale under the direction of skilled specialists.

A remarkable 'rider' placed upon the Act is a provision for taxing corporations one per cent on all net income in excess of \$5000 per annum. It is, as Mr. J. Warren Keifer, of Ohio, showed, anomalous to combine a direct tax with a bill which primarily is intended to raise revenue by the indirect system. The basal mining law of the land, however, is only a 'rider' upon an Act for the right of way of ditches. Congress is all powerful within a few elastic Constitutional restrictions. That the corporation tax will prove injurious is commonly conceded. It will hit the insurance companies a severe blow and raise the rates; it will encourage consolidations under holding companies, which are exempt; it will stimulate the raising of capital and the absorption of earnings by

bond issues. Tax-dodging is a game of world-wide interest; the bull-movement of American stocks during the last six months is currently attributed to the tax-dodgers of Europe investing in American securities. One can but marvel at this feature being tacked upon the tariff, considering how inevitably it must fail of its avowed purpose. It will prove a most obnoxious part of the new law.

Signs of revolt against the Party leaders were shown in the refusal of seven Republican senators to record their votes in favor of the bill as it finally issued from conference. No such defection was ever witnessed before in connection with previous tariff legislation. It is said that these senators, headed by Mr. J. P. Dolliver, are now attempting to organize a faction with the avowed purpose of securing control of the Republican Party. This is inspired in the belief that the temper of the people presents the alternatives of schism or reform.

Mascot Copper Company.

Interest in the flotation of the Mascot Copper Company has become so keen as to demand a statement concerning its activities. The central offices of this company are in San Francisco, and its directors are scattered all the way from the Atlantic to the Pacific. Most of them are well known men, who stand high in their respective communities. The property of the corporation consists of 38 mining claims near Dos Cabezas, Arizona. The veins are said to vary from about 4 to 20 feet in width, and are claimed to average about 5 per cent copper, with gold and silver in variable amounts. Development to date aggregates about 7000 lineal feet, consisting chiefly of tunnels. The expenditure, of which this development is the visible fruit, is said to have been approximately \$300,000, or nearly \$43 per running foot. The equipment on the property consists of a small amount of machinery such as befits a mine in the early prospect stages, the most important being two Rand air-compressors. Some of the veins have been cross-cut about 500 feet below the outcrop. This is the deepest development. No driving has been done, and consequently no data have been obtained concerning probable available ore reserves below the carbonate zone. These statements are based upon data furnished by the assistant general manager for the company.

The Mascot Copper Company was incorporated under the laws of Arizona in July 1907, with an authorized capital stock of \$10,000,000, all of which was immediately issued to the Western Finance Company in payment for the properties and the improvements turned over. Stevens' 'Copper Handbook', for 1908, states that the "lands, circa 43 claims, including property formerly held by Dos Cabezas Consolidated Mines Company, (are) said to be held under bonds aggregating circa \$500,000." The Western Finance Company is the promoting concern, and is controlled by Messrs. T. N. McCauley, John A. Street, and E. A. Ealey. Mr. McCauley is the general manager for the Mascot company, and Mr. Ealey is resident superintendent at Dos Cabezas, Arizona. The Western Finance Company returned 250,000 shares of the Mascot stock to the

Mascot company with which to raise working capital. Of this quantity approximately 75,000 shares are reported to have been sold. Stock in the Mascot Copper Company was originally sold at \$3 per share; the price was arbitrarily advanced to \$4, and later to \$5. The methods of attracting attention have been of a spectacular character—an elaborate banquet at the Fairmont hotel, in San Francisco, another for the benefit of the merchants in Chinatown, palace-car parties to visit the mine, all magnanimously paid for by the corporation. These are the methods which have been generally identified with get-rich-quick schemes.

Evidence of the existence of large bodies of commercial ore has not been given to the public. Reports by Messrs. W. B. Tibby and John W. Gillingham, have been made but not printed for distribution. The accessible data from their reports appear to us inconclusive. A statement issued over the name of Mr. Gillingham gives a brief review of a few general geological characteristics of the immediate region, and continues, "The different veins, which I believe are fourteen in number, have to the mining engineer most favorable indications of mineralization and vein structure, and from the fact that these veins already disclosed by open-cuts and shallow shafts on the surface in so many places, and that the development work already done verifies the expectations aroused by surface indications, I would say in conclusion that from all the evidence at hand I believe the veins will be highly mineralized at depth, and that the mineral wealth at their intersection will be an immense profit to the fortunate owners." Such rambling comment is a vastly different thing from the careful and elaborate geological analysis which the world now expects as a preliminary to the opening of great mines, and it manifestly fails to answer the questions which a serious investor would ask. It is of the type of glittering generalities which are characteristic of boom reports and fake promotions. If the gentlemen promoting this concern have data warranting the outside public in assuming one-half the expense for 7½ per cent of the ownership of the property, those data have not been made public.

The president of the company is Mr. H. H. Evans, a politician of unsavory record in Illinois, one of the well known leaders of the 'Senate Combine' who was one of the promoters of the defunct International Mercantile Agency, with which Mr. Thomas N. McCauley was also identified. This association with a concern that ended in scandal, reflects strongly upon the new concern which is being promoted along lines which are so characteristic of those which are snares for the unwary.

How far it is worth while to warn investors is a question on which there is difference of opinion, but it does seem surprising that a corporation having no large measurable tonnage of ore developed can sell some \$300,000 worth of stock in a company of which 75 per cent of the shares, giving absolute control, remains in the hands of the promoters. If people wish to promote properties on that basis and others care to 'invest' money on such terms, there is no law to stop them, but it is not sound business.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

WILLIAM KNOX is at Igo, California.
 BERTRAM HUNT is in San Francisco.
 F. L. BOSQUI has left today for London.
 H. KILBURN SCOTT has left for Bulgaria.
 P. A. BABB, of Mexico City, is in Boston.
 C. H. NAZRO was visiting San Francisco.
 W. F. FERRIER is on a trip to San Francisco.
 FRANK H. PROBERT is at Houghton, Michigan.
 ELWYN W. STEBBINS is in Spokane, Washington.
 HENRY COLLENSON has gone to British Columbia.
 S. A. WORCESTER has returned to Victor, Colorado.
 C. F. NOURSE is at the Pilares mine, Sonora, Mexico.
 R. E. RAVEN has gone from Boundary, B. C., to Toronto.
 W. L. COBB will be at El Tino, Mexico, until September 1.
 C. D. WILKINSON has left Goldfield, Nevada, for New York.
 ERIC H. A. NORDIN, of Sacramento, was in San Francisco.
 H. FOSTER BAIN is visiting Denver and other Colorado points.
 H. A. SHIPMAN is in London from the West Coast of Africa.

MARCUS C. H. LITTLE, of London, England, is at Cobalt, Canada.

ANDREW WALZ has accepted a position at the Planet mine, Planet, Arizona.

SELWYN GOLDSTEIN is examining mines in Guerrero, Mexico, for English clients.

H. C. CUTLER has returned to Goldfield, Nevada, from Grass Valley, California.

W. H. HERDSMAN left London, August 6, for Nova Scotia to examine iron deposits.

E. L. OLIVER, superintendent of the North Star cyanide plant, is visiting Oakland.

R. C. RUCKER is at Durham, California, on leave of absence from Zaruma, Ecuador.

J. PARKE CHANNING returned to New York from Europe last week on the S. S. *Cleveland*.

R. H. BURROWS is now with the Moctezuma Copper Co. at Pilares de Nacozari, Sonora, Mexico.

HENRY LANCASTER, of Wallace, Idaho, has been on professional business at Murray, in that State.

W. S. NOYES has gone to Denver from Chicago. He will return to San Francisco about August 28.

NORMAN CARMICHAEL has been appointed general manager for the Arizona Copper Co., Clifton, Arizona.

L. S. AUSTIN is at Seattle, and will return to Houghton, Michigan, by way of Portland, Salt Lake, and Denver.

JAMES H. HOWARD, general manager for the Amparo Mining Co. of Etzatlán, Jalisco, Mexico, is in Philadelphia.

J. E. SPURR has finished an examination of the properties of the Ray Consolidated Copper Co. at Kelvin, Arizona.

LAWRENCE B. ADAMS, manager for the Guanajuato Amalgamated Gold Mines Co., La Luz, Mexico, is in Europe.

WALTER W. WISHON, manager of the Octave mine, Wickenburg, Arizona, is examining mines in Yavapai county, that Territory.

HERMAN A. PROSSER has associated himself with ARTHUR L. WALKER in partnership. They have opened engineering offices at 42 Broadway, New York.

G. H. GARREY, J. VOLNEY LEWIS, MARDEN W. HAYWARD, and W. H. GRANT are making an examination of the Cla. Minera de Peñoles properties at Ojuela, Durango, for Spurr & Cox.

A. C. LUDLUM, J. F. MCKENZIE, WILLIAM MARSHALL, A. N. WORTHINGTON, G. R. E. KENNEDY, and K. E. KENNEDY have been visiting the properties of the Compton Gold Dredging Co., in eastern Quebec.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Arizona United Mining Co. expects to complete its 125-ton smelter at Johnson in the early part of November. The company has placed orders for a large amount of supplies and coke, and has let contracts to have them hauled from Dragoon to the mine. The contract calls for the delivery of 25 tons of coke per day at the smelter. William Robinson is superintendent.—W. F. Staunton, manager for the Tombstone Consolidated Mines Co., was in Tombstone recently to arrange for the purchase of a large compressor plant. At the mine ore is being taken from the 700 and 800-ft. levels and two or three carloads of concentrate shipped per week.—Charles Purdon and James Hart, of Tombstone, have bonded the Abril-Herrera group in the Dragoon mountains for Colorado capitalists. There are six claims in the group, and several small bodies of oxide and carbonate ore have been opened by surface cuts. The option runs for two years and calls for a \$30,000 payment if taken up at the end of that time.

GILA COUNTY.

The shaft of the Arizona-Michigan is down 500 ft. and cross-cuts started north and south from that point. The management expects to tap the orebodies found in the upper levels in 100 ft. with the south cross-cut, and in 300 ft. with the north. N. A. Nelson is superintendent.—The National Mining Exploration Co. has completed the installation of a compressor with a capacity of 800 cu. ft. per minute at the Williams shaft, which is now down 110 ft. The Fumarole mine of the same company is closed down temporarily for the installation of new machinery. F. A. Woodward is manager.

GRAHAM COUNTY.

J. Blackstein, of Clifton, has secured a three years option on the Gold Belt property and will erect a 20-ton reduction plant at the mine. There is a large amount of \$7 ore blocked out in the mine, with occasional streaks of high-grade.

MARICOPA COUNTY.

In a report on the Vulture mine, 15 miles south of Wickensburg, the management states that the mine has been completely unwatered and cross-cutting started on the 600-ft. level. On the 400 and 500-ft. levels the drifts have been re-timbered and ore is being blocked out for stoping. In the mill 20 stamps have been put in running order and will be kept dropping on ore from the development work. A. R. Mackay is manager.

MOHAVE COUNTY.

The Crowell mines on Wright creek have been bonded and will be prospected by diamond-drilling.—A contract has been let to sink the Treasure Hill shaft 100 ft. from the 140-ft. point.—At the Horseshoe mine west of Cerbat a contract has been let to sink the shaft 300 ft. deeper and drive 700 ft. of drifts and cross-cuts.

CALIFORNIA.

CALAVERAS COUNTY.

It is understood that W. G. Hammond and associates of Butte county have made arrangements with the Hayward and Hobart heirs and C. D. Lane to take over the Utica mine at Angels Camp, together with the holdings of the Union Water and Angels Light & Power companies.

ELDORADO COUNTY.

(Special Correspondence).—At the Gold Crown an 8-ft. vein assaying from \$8 to \$12 per ton has been opened.—The Landecker has resumed operations with a small crew of men. It is expected to start the mill within a few days. Howard C. Plummer is superintendent.—It is reported that the Larkin and Alderson mines will be re-opened under the management of Charles H. Dunton. The Alderson will be worked through a cross-cut from the Larkin.—Phillip Hickey is arranging for active work at a number of claims on the Hickey ranch.—The Boden gravel de-

posits on the Boden ranch have been purchased by J. E. Johnson. A hydraulic mine permit has been requested from the Débris Commissioners.—A number of properties in the Shingle Springs district are active, with a good production maintained.

Placerville, August 16.

At the Mt. Pleasant mine near Grizzly Flats the water has been lowered to the 500-ft. level. The development work is at present confined to the 300-ft. level, but cross-cuts from the shaft will be started to the vein when it is drained to the 600-ft. point.—On a test lot of ore from the Morey mine the average return was over \$100 per ton.—Operations are to be resumed at the Martin mine this fall.

INYO COUNTY.

At the Cerro Gordo mine of the Four Metals company new buckets are being added to the aerial tram to handle the increased output. About 300 tons of ore averaging 52% lead and 50 oz. silver are stored at Keeler till the smelter shall resume operations. There are also 1400 tons of slag running 13% lead and 10 oz. silver ready for treatment.—The Inyo Mines Syndicate is sinking two shafts on its property at Hummer, seven miles west of Olancho. W. G. Scott is in charge of the work.

NEVADA COUNTY.

The Idaho-Maryland is stoping on the 500 and 600-ft. levels. Some excellent ore is being opened at both places. The raise from the 1200-ft. level of the Mountaineer for the new shaft is up over 50 ft.—Fred Clarke, of San Francisco, has bonded the Twin Sisters mine near Snow Point. Two adits have cut the vein, which is on a slate-serpentine contact near the surface, and a lower adit has been started that will give 500 ft. of backs. George Hegarty is in charge of the work.

SAN BERNARDINO COUNTY.

The raise which recently opened phenomenally rich ore on the Oro lease of the Big Chief ground continues in a body of good milling ore, with occasional streaks of high-grade.—The north drift on the Oro Belle is now in nearly 400 ft. with good ore the entire length. On the 100-ft. level the cross-cut is expected to cut the vein within the next few weeks.—Work has been resumed on the Oro Belle Extension No. 1 claim. The ore so far opened is of milling grade, but will not pay to ship outside the district.

SHASTA COUNTY.

H. F. Musser, manager for the Western Exploration Co., brought nine gold-bricks, valued at \$13,400, to Redding as the result of the July run.—The home of Marlon M. Beckwith, superintendent of the Quartz Hill mine, was completely destroyed by fire. The loss amounted to \$2500.—M. Russell sold his interest in the Mother Lode group of claims west of Redding to Los Angeles capitalists.—An organization known as 'The Farmers' Protective Association' has been formed at Olanda to compel the smelters to pay damages for the supposed injury.—The Noble Electric Steel Co. shipped 20 tons of pig iron to the foundries at Redding from its plant at Heroult. The iron is of an excellent grade for foundry purposes. The Northern California Power Co., which is closely allied with the Steel company, has turned on the water to generate 5000 hp. at its new hydro-electric plant near Manton.

SIERRA COUNTY.

R. H. Chase has succeeded W. L. Stevenson as manager for the syndicate that was recently formed to operate the Gold Canyon, Happy Jack, Happy Jack Extension, Steamboat, St. Elmo, Townsend, Golden Crown, Golden Crown Extension, and Gold King claims. There is a 10-stamp mill on the Gold King property which is credited with a production of \$45,000.—Contracts have been let to drive the adit at the Eureka claim at Forest 100 ft., and that at the Bixby 125 ft.—At the Slattery gravel claims the old adits and raises are being cleaned out and re-timbered. H. Eckart is in charge of the work.—C. M. McMeekin is to succeed Mason W. Mather as manager of the Plumbago mines early in September. Mr. Mather will still continue as vice-president of the company.—In cleaning out the old adit at

the Slate Castle-Jaffa mine a 6-ft. vein of good looking ore has been opened.—The Arnold brothers, of Goldfield, have bonded the Ramshorn, First Chance, and Forest claims and started an adit to open the vein at a depth of 300 ft. A number of good assays have been obtained from a surface sampling of the vein.—The adit at the Eastern Cross near Alleghany has cut the ore-shoot at a depth of 50 ft.—James E. Deal has opened some excellent gravel on his group in Clark's canyon.

SISKIYOU COUNTY.

The clean-up of a 29 days run of the 2-stamp mill recently installed by the Elk Creek Mining Co. at the Colburn mine amounted to \$3300.—An 80-ton lot of ore from the Last of the Mohicans mine near Fort Jones milled over \$20 per ton. James Morrison is in charge of the work.

TUOLUMNE COUNTY.

Wayland Avery, the representative of the Providence Consolidated Gold Mining Co. of New York City, owner of the Providence and Consuelo mines at Tuolumne, is now visiting the properties. Mr. Avery is to be on the ground several months, and it is understood the company would consider a favorable offer for its holdings.—The Karmac Mining Co. is installing a new surface plant at its property above Jamestown.—Plans are under way for the resumption of work at the Clio and Tarantula mines. T. C. Crawford is manager.—The Yrma Gold Mining Co. has been organized at Jamestown to conduct a general mining business. The first effort of the company will be directed to the Josephine mine near Algerine.

YOLO COUNTY.

C. Perkins has filed an action at Woodland to recover damages in the sum of \$15,600 from the Bay & River Dredging Co., alleging that the defendant company, in 1908, dredged through a levee of a farm adjoining his in order to get onto land that was to be reclaimed, and that the gap in the levee was not closed, allowing his land to be flooded last January, leaving deposits of sand, washing out roads, and starting a troublesome growth of willows.

COLORADO.

PUEBLO COUNTY.

Over 500 men are idle as the result of the strike of the furnace-men at the zinc plant of the American Smelting & Refining Co. at Pueblo. The strike is on account of the refusal of the company to grant the scale of wages in force two years ago, which was an advance of 25c. per day over the present rate. The plant is under the guard of armed deputies.

SAN JUAN COUNTY.

The Allerton Mining Co., operating the Joe and John group, shipped four cars of ore to the Durango smelter. This ore was taken from the upper workings, but the company has driven an adit 500 ft. to cut the vein at depth, and hopes to open a series of lower levels in a short time.

TELLER COUNTY.

The annual report of the Mary McKinney Mining Co. shows a profit for the year of \$67,827.—The return on a two-car shipment from the Shurtloff mine was \$84 per ton.—The Elkton Consolidated Mining Co. has declared its regular bi-monthly dividend of \$37,000, payable August 24.—The shaft on the Buckhorn claim on Carbonate hill has been completed to a depth of 208 ft. and cross-cuts started to the vein.—A raise has been started from the fourth level of the El Paso mine for a new working shaft. John Nichols is superintendent.

IDAHO.

IDAHO COUNTY.

Operations are to be resumed at the Graham-Ross property near Newsome. This mine has been idle for the past two years.—A 350-ft. adit with a 50-ft. cross-cut has been driven on the Mackey property. A 20-ft. vein has been opened on the surface, from which good assays have been obtained.—Considerable work is being done at the Leggett Creek placer claims this season. James Surridge has a force of men working on a 175-ft. bank.—At the Little

Butte property of George Widmeyer, over 1000 ft. of development work on the vein has been done at a depth of 250 ft., and a large tonnage of ore that assays over \$14 per ton stored on the dump.—A trail is being constructed by the forest rangers from the Elk City-Orogrande wagon-road that will furnish a winter route to the Four Mile district.—The Penn-Dixie Mining Co. has cut another ore-shoot in its No. 3 adit. The company has now 2400 ft. of development work on the vein and a large tonnage of ore on the dump. William L. Sendker, the superintendent, is authority for the statement that the company will erect a mill at the mine in the near future.—A 500-ft. shaft is to be sunk on the North Star property.

NEZ PERCE COUNTY.

The Idaho Mining Co., operating in the Pierce City district, is completing a second dredge for the high placers adjoining the town of Pierce, and it expects to begin operations in a short time. This property was acquired four years ago and the first dredge was placed in operation in 1907.—The Bunker Hill & Sullivan Mining & Smelting Co. has purchased the Black Lead property in the Lolo Pass district of the Bitter Root mountains from L. F. Williams. Considerable development work has been done on the property and some high-grade copper ore opened. The price was \$50,000.

OWYHEE COUNTY.

A force of men has been started on the Big Sugar Loaf property.—The 950-ft. adit at the property of Michael Rock, adjoining the Big Sugar Loaf, is being driven ahead to tap the second vein. An average assay of the 12-ft. vein first opened was \$4.50 per ton.—New machinery has been installed at the property of the Wennersten Mining Co. and arrangements made with the power company to furnish electricity.—A boarding house and surface plant is being erected at the Noble mine. Angus McDonald is in charge of the work.

SHOSHONE COUNTY.

Work is to be resumed at the Old War Eagle group on Placer creek in the early part of September. Some \$30,000 has been spent on the property and \$20,000 more has been raised to continue the work. Charles F. Ruddy is manager.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—Eastern capitalists have leased 100 acres of the Murphy land at Galena and are preparing to sink a shaft on the property.—A part of the Clermont land has been leased and the lessees have placed a drill on the property to prospect it. The Clermont company has secured the High Tariff mill and is moving it to its property.—A new air-compressor and sludge tables have been added to the equipment of the Childress mill. The company is working in a disseminated ore.—The Charlotte Mining Co. has opened a rich deposit on the Matthews land and is repairing the old mill on that property.—The Gerster Mining Co. has been adding new equipment to the Southside mill.—The W. P. Clements mill is being repaired and a number of properties in that neighborhood reopened.—The Lehigh Circle Mining Co. has sunk 3 drill-holes which have cut some zinc and 70 ft. of ground containing lead ore. This land has been but slightly worked as there is a heavy flow of water there.

Galena, August 16.

MICHIGAN.

The results obtained in the experimental test of Superior ore at the Calumet mill have not been publicly announced but from unofficial sources it is learned that a very much better extraction was made by the method there in use and that the recovery was about 7 lb. mineral, the equivalent of 3 lb. refined copper greater than that obtained in the Atlantic mill. A proper readjustment of the milling machinery in the Atlantic mill with particular attention given the wash department is now being made.—The Quincy Mining Co. is planning an increased output to keep the stamps recently installed working to their full capacity.

MISSOURI.**JASPER COUNTY.**

(Special Correspondence).—The Holdout Mining Co. has just started the new 250-ton mill on the Guinn land near the Incline and Osceola.—Four properties have just been started in the Duenweg district.—The Ave Maria Co., south of Webb City, is taking up a 10-ft. stope of rich ore in the drifts.—Gallagher & Cerke on the Taylor & Glover land west of Joplin have opened up an old shaft where ore occurs at 117 ft. Drifts have been started. There are 14 drill-holes on the lease, put down several years ago before the water in the camp could be easily handled. This difficulty no longer exists as a number of companies are pumping in the vicinity.—On the Shifferdecker land another good find has been made by the Angora Cat Co., in the second hole sunk on the ground. The ore is found from 162 to 177 ft. and from 185 to 201. This company has cleaned out an old shaft from which drifts are being run to the new discovery.—The Hercules mill on the Luke & Ash ground now under construction will be the largest in the Joplin camp with a capacity of 500 tons per day.

Joplin, August 16.

NEWTON COUNTY.

(Special Correspondence).—The Halloween and Sunrise, two new plants in the Spring City camp, began operation last week. Several drill-holes are on the Halloween lease and the shaft has cut ore at 100 ft. The Sunrise is a new plant built to replace the one burned this spring and is an improvement over the former mill.—The Microbe is another new plant recently finished in the Spring City camp. Ore is found here at 100 ft. in a rich blanket formation.—The old No. 1 mill at Roaring Springs has recently been leased and is now used to treat tailing. Two concentrating tables have been added to the regular equipment.—The Watauga Mining Co. has recently erected a plant at Roaring Springs upon a lease with a promising orebody. Before the mill was built the ore was cleaned on hand-jigs with good results. The ore is free and consists of galena and zinc-blende, the galena being found in large chunks as well as in the fine crushed particles.

Spring City, August 17.

MONTANA.**FLATHEAD COUNTY.**

The Brick and Brannagan mine at West Fisher, 35 miles southeast of Libby, has been sold for \$125,000 to the Fisher Creek Mining & Smelting Co. The sale involved a cash payment of \$2500 with others to follow at stated intervals. There is a 10-stamp mill on the property which is credited with a past production of \$85,000.

NEVADA.**CLARK COUNTY.**

A station has been cut at the 300-ft. level of the Princess claim of the Spokane-Searchlight company and a small hoist installed at the surface of the shaft. Cross-cuts will be run into the hanging and foot-walls and drifts run on the vein from the 300-ft. level. Richard Lloyd is superintendent.—A gasoline hoist and new head-frame has been installed at the Duplex-Contact property at Searchlight. An engine-house and blacksmith shop have also been completed. The shaft is now down 100 ft. and cross-cuts will be driven to the vein.—The Quintette Mining Co. has started a drift on its property that will give 250 ft. of backs.

ESMERALDA COUNTY.

From the 430-ft. level of the Collins shaft at Luckyboy both east and west cross-cuts have opened bodies of shipping ore.

HUMBOLDT COUNTY.

The National mine at National continues to ship high-grade ore of sensational value. Some of the ore taken out of the high-grade streaks assayed \$70 per pound. In the Combination adit the Stall brothers have opened five shoots of ore.

LINCOLN COUNTY.

(Special Correspondence).—It is reported that the shaft

at the Quartette will be sunk to the 1500-ft. level at an early date. A large body of shipping ore is being opened on the 1100-ft. level. Steady shipments are maintained to the Selby smelter.—Sinking has been resumed at the Portland. The shaft is down 100 ft.—The Parallel company is to sink below water-level and is arranging for the installation of a pump. A considerable quantity of good ore is blocked out in the upper levels.—The Homestead has granted two leases.—At the Trio mine copper ore and ruby silver are being opened.—On the Chester lease at Crescent a streak of ore running \$300 per ton has been intersected in the 4-ft. vein.—Several important discoveries have been recently made in the Crescent district, and a large number of leases are working.

Searchlight, August 12.

NYE COUNTY.

The Bath lease at Manhattan opened a 2-in. streak of high-grade ore on the 30-ft. level. The drift has been run 16 ft. on the vein, which assays \$175 per ton.—The Aurora-Bullfrog Mining Co. at Springdale is planning the erection of a 200-ton mill on its property. The company has a large amount of \$9 ore opened and will sink another 100 ft. Joseph Murphy is superintendent.—A number of prospects at George's canyon are opening veins of ore, surface samples from which have assayed high. On the Tonopah Drug Co.'s group a number of assays have been made on surface material that go over \$100 per ton.—On a 25-ton shipment from the Gillespie lease on the Jim Butler ground at Tonopah the net return was \$412. The ore was taken from the dump, which would not pay shipping expenses when mined six years ago, and was treated in the Belmont mill at Miller. There is considerable more ore of this grade on the dump and the lessees are opening a 6-in. vein at the bottom of the 150-ft. shaft that assays \$100 per ton.

WHITE PINE COUNTY.

In a 106-ft. winze from the No. 1 adit the Hulse Leasing Co. opened a body of carbonate ore that assays 40% lead and 20 oz. silver per ton. The discovery was made on the Ontario claim of the Ely Hidden Treasure Co. A lower adit is being driven toward the orebody.—Five tons of 30% copper ore has been sacked for shipment on the Johnson lease on the Ely-Calumet property.

NEW MEXICO.**GRANT COUNTY.**

A 60-lb. lot of turquoise rock was taken from a 36-ft. shaft at the Cameo mine of G. W. Robinson at Hachita.

OTERO COUNTY.

The plant of the Orogrande Smelting Co. at Orogrande is practically completed and the manager, J. J. Murry, is in the field buying ores.—Several carloads of ore have been shipped by Charles H. Knibbs from the Delusion mine to the El Paso smelter.—Culver & Downs have cut several veins of ore on their property, but have made no attempt to stope any of the ore.

SOCORRO COUNTY.

The aerial tram of the Mistletoe Mining Co. at Kelly is nearly completed, and it is expected to have the mill running in a short time. An adit has been started on the Helen Cross claim to tap the orebody at greater depth. W. F. Gordon is manager.—The German Mining Co. has advertised for bids to drive a 900-ft. adit on its property in Kelly gulch. Power will be furnished by the Tri-Bullion Mining & Smelting Co.'s plant.

OREGON.**JOSEPHINE COUNTY.**

At the mill of the Greenback mine 15 stamps have been put in operation, and it is the intention of the lessees to have all 40 dropping in a short time. J. P. Anderson is in charge of the work.

LAKE COUNTY.

J. F. Cutler and associates have purchased the mining property of William A. Schauers on Mt. Hoag.—McVey brothers are sinking a shaft on the contact on their property near Goldberg.—An excellent orebody was recently

cut in the Goldberg Butte mine.—The shaft of the Jumbo Chief is being re-timbered and the company plans to sink to the 200-ft. level.

UTAH.

BEAVER COUNTY.

A new 200-ft. double-compartment shaft is to be started at the Hub mine in the Star mining district. A good showing of copper, lead, and silver ore has been obtained by surface work on this property. John Thompson is manager.—The Beaver Carbonate Mining Co. is to construct a new milling plant at its mine near Frisco. The company has opened a body of milling ore on the 700-ft. level that is 20 ft. wide. A raise from the 700-ft. level has been driven 200 ft. in ore. Grant Snyder is manager.—Assays from samples from the face of the drift run at the 140-ft. level of the Black Rock shaft ran 40% copper, \$3 gold, and 16 oz. silver. The vein is on a contact and is 4 ft. wide. Walter James is in charge of the work.—The shaft of the Cupric Mining Co. has opened several small bodies of ore that have assayed as high as 35% copper.

DAVIS COUNTY.

The Burro Mining Co. is developing a group of eight claims in the Bountiful mining district. An adit has been driven 250 ft. toward the vein, which is on a contact between quartzite and limestone. The company has built nine miles of road to the mine and opened the vein by a number of open-cuts and winzes.

IRON COUNTY.

The Gold Springs Mining & Power Co. has let a contract to the Westinghouse Machine Co. for the installation of two 16 by 18-in. three-cylinder gas engines, two 190-hp. gas producers, and two 100-kw. Westinghouse generators to be installed at the Jennie mine at Gold Springs. The company is to let contracts for mine equipment and cyanide plant machinery. Charles A. Short is manager.

JUAB COUNTY.

H. J. Meyer, manager for the Trout Creek Mining Co., brought a number of samples from the company's property to Salt Lake for assaying. The ore is very complex, containing zinc, bismuth, copper, silver, and gold.—The Utah mine at Fish Springs is to resume paying dividends. Payments were suspended from the first of the year to purchase part of the Last Chance claim and to install a new 50-hp. gasoline hoist. The company is shipping three cars of ore per month that averages over \$100 per ton.—The Hannibal Mining Co. has been formed at Provo to work a group of claims in the Tintic mining district.—The Tintic smelter has resumed operations after a few weeks shut-down for repairs and the installation of new machinery. The mines are again shipping ore to the smelter, which is running satisfactorily.—The International Smelting & Refining Co. declared a dividend of 1½c. per share, payable September 1.—At the Colorado mine near Eureka a 30-ft. winze has been sunk in ore from the 300-ft. level. The Colorado company declared the regular monthly dividend of 8c. per share, amounting to \$80,000.—The Sioux Consolidated declared a dividend of 7c. per share, payable August 20.

SALT LAKE COUNTY.

The stock of the company operating the Prince of Wales mine at Alta has been increased from 10,000 to 30,000 shares. The company is now shipping 40 tons of ore to the Taylor & Brunton sampler and is increasing its stock to raise money for more extensive development.—The Yosemite Mining Co. has been organized to work the Yosemite, Cluster, and Mississippi groups at Bingham.—Samuel Newhouse has abandoned Edward Fink in his attempt to make the Fink smelter a success and the plant at Garfield has been closed down. One trouble with the furnace was with the tuyeres, no material being found that would successfully stand the heat.

SUMMIT COUNTY.

The Silver King Consolidated Mining Co. has at last cut the contact for which they have been driving for some time, and opened a body of silver chloride and bromide

ore with some galena. The company sunk an 1100-ft. shaft and cross-cut 2000 ft. From the face a 500-ft. winze was sunk and a short cross-cut run to the contact. A number of veins were cut in this work, but none large enough to be of commercial value. Solon Spiro is manager.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—The Washington-Meteor mine has been leased by Davis & McDowell, who recently acquired the Blinn group.—In Red Mountain district the Chihuahua Lead & Silver Mining Co. is driving a long adit to cut the vein exposed on the surface of its property.—The Chelan Consolidated Copper Co. has driven an adit into Red mountain 1300 ft., and opened a 5-ft. vein of high-grade ore at a vertical depth of 1500 ft. New York people are the principal ones interested. The company will drive the adit 1200 ft. farther, to intersect another vein, from which some excellent ore was taken in the upper levels.

Wenatchee, August 17.

FERRY COUNTY.

(Special Correspondence).—About 2000 tons of ore have been shipped by the New Republic Mining Co. to date. The management reports two veins of shipping ore cut south of the old workings, one between 4 and 5, the other between 2 and 3 ft. wide.—The Black Tail Mining Co. at Republic has shipped 12 carloads of ore under the present management and is now figuring on installing new machinery.—The lessees of the Ben Hur mine have shipped four carloads of \$22 ore and have two more ready for the smelter.—The South Republic Mining Co. has opened a stope 125 ft. below the adit level.—The Grand View Mining & Milling Co. has filed articles of incorporation at Spokane to operate the New York, Ophir, and Independent lode claims, about three miles south of the international boundary line, near Danville. A shaft has been sunk to a depth of 80 ft.—The Kettle River Mining Co., near Rockcut, is sinking on a 5-ft. vein of rich galena ore. The mine has been equipped with a steam-hoist, compressor, machine drills, and pump.—The Pearl Consolidated Mining Co., operating its mine on a leasing system, has reduced the indebtedness to \$5000 and has \$3400 in the treasury for running expenses. As no satisfactory offers have been made to lease the mine since the former lease expired August 1, the property may be worked under the company's management.

Republic, August 16.

OKANOGAN COUNTY.

The shaft of the Molson Mining Co. at Molson is down 105 ft., with a station cut at that point. The company will install a hoist and develop the vein from this point.

STEVENS COUNTY.

(Special Correspondence).—Ten tons of hematite were forwarded from the Vigilant mine to the Valley smelter. About 5000 tons per year have previously been shipped to the Idaho and Coast smelters.—The North American Marble Co. has erected a surface plant and dwelling houses for the men at its quarry near Valley. The beds are extensive and furnish a variety of shades.—The Forrest Mining & Milling Co. has completed the installation of a 10-ton Hesse cyanide plant at the Easter Sunday mine.—A diamond-drill with a capacity of 600 ft. has been ordered by the First Thought Gold Mines, Ltd. The company is shipping four carloads of ore per week to the Trail smelter, and is expected to commence building a cyanide plant at the mine shortly. Alexander Sharp is manager.—The shaft at the Copper-Butte is down 150 ft. in a vein of copper-gold ore, and a contract let to sink another 100 ft. At the 250-ft. level drifts will be started on the vein and stoping commenced.—The Pierre Lake Gold & Copper Co. has been incorporated to develop the Commonwealth group. Frank Werhardt, F. L. Newton, and W. Nelson are the incorporators.—The Imperial Copper Co. of Chewelah is installing a boiler, pump, and hoist at the mine. P. J. Bonner is in charge of the work.—Operations are to be resumed at the Montezuma group, eight miles west of Chewelah. Warner Apelson, of Portland, is the principal owner.—The High

Grade Silver & Copper Co. has been organized at Chewelah. There is a 110-ft. shaft on the property and the company plans to sink this and cross-cut at a lower level. T. F. Hertzell is manager.—The drift at the Bornite mine near Newport is in 800 ft. on a 2-ft. vein of excellent ore.—At the Treadwell mine near Northport a shaft is being sunk on an 8-ft. vein, 30 in. of which is high-grade galena ore. H. W. Jackson is manager.—The return from the Boulder smelter on a shipment of tungsten ore from the Tungsten King mine in the Deer Park district was \$460 per ton.

Colville, August 14.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The differences of the B. C. Copper Co. and its miners are to be settled at an early date. The company has agreed to give the union the same recognition and pay its members the same wages as the Granby and other operating properties in this district are doing. The questions between the miners and the company are now under discussion, and it is likely that a working arrangement will be the outcome. Local mining men look for a resumption of work at both the B. C. Copper and New Dominion mines early in August. There is a sense of relationship between these companies since the Lewisohn interests have become identified with the B. C. Copper Co. —The new slime mill at the Jewell mine will be completed in a week or ten days, when the process which proved so successful on a small scale will be put to a working test. There is a big body of concentrating ore ready for stoping in the Jewel, and it will prove a boon to the men interested if they can secure the desired recovery of metallic content with the new system. A lead nearly 90 ft. wide has been uncovered on the Le Roi claim, West Fork, where development is now being carried on. The lead has been exposed for several hundred feet. Two shafts are being sunk and are now down 75 ft. An average assay of the orebody returns 47% iron, 30% sulphur, 2½% copper, and small quantities of gold and silver. The tunnel on the Woodburn property of the Phoenix Mining, Smelting & Developing Co. has been driven 300 ft. toward the orebody. —Extensive work is being done on the pegmatite dikes of the Big Bend district. It is only a matter of time until development and transportation will open a big mica-field in this district. The companies who own the mica deposits are petitioning the Government for better roads and trails. A strike of copper glance, assaying 64% copper, and 48 oz. silver per ton, has done a lot toward dispelling the illusion that no appreciable amount of mineral might be found in the Coast Range. A vein 8½ ft. wide was found near Douglas channel by an old prospector, and work is now being done on it. The find is considered of importance. That the Portland Canal mining district will prove an important factor in the progress of mining in this province is shown by some assays recently taken on the Red Rock group, where active work is now in progress. Average Red Cliff ore assayed 1.90 oz. gold; 2.60 oz. silver, 17.80% copper; total value per ton \$72. On the Montrose claim the auriferous mudic ore assayed 6.30 oz. gold, or \$126 per ton. The entire Red Cliff vein is approximately 100 ft. wide, that on the Montrose from 35 to 40 ft. A strike on the Richard II property last week in a 4-ft. vein assayed \$250 in silver and \$60 gold. The Richard II is controlled by the Stewart Mining Co. of Victoria.

Rosslund, August 14.

The British Columbia Copper Co. has purchased the claims adjoining the Jackpot group from D. Oxley. The engineers of this company are examining several properties at Kamloops.—The Alaska Mining Co. is to resume operations on the Buster and Alaska claims on Wallace mountain. A 35-ft. shaft has been sunk on a vein of lead-silver ore.—The Nicola Valley Coal & Coke Co. have purchased a 30-drill Rand compressor. The output of the company is 400 tons of coal per day at present and the installation of this additional power will increase it to 1000 tons per day.—The Lelitch Collieries Co. has commenced work on a new property at Police Flats east of Passburg.—A contour map of the Sheep Creek mining

district has been issued by the Geological Survey.—Samples taken from the Brown-Bulldog mine between Princeton and Hedley assayed 5% copper, 14% zinc, 8 oz. silver, and \$8 gold.—The Lucky Jim Mines, Ltd., is preparing to ship 200 tons of ore per day from the Lucky Jim mine near Kaslo. The ore is zinc-blende and averages 35% zinc.—The force at the Snowshoe mine has been increased and the output of the mine raised from 600 to 700 tons of ore per day. The company is mining the ore with an electric stripper.—The Columbia Copper Co. is opening a large body of bornite ore on its property in the Similkameen district.—Ley & Douglas have resumed operations on the Alice mine near Creston.

A contract is to be let to sink a 200-ft. shaft on the Blue Bird mine near Rosslund. The mine has previously been worked by lessees operating on a percentage basis. The net return on a shipment of 10 carloads of ore was \$30 per ton. L. C. Carter is manager.

ONTARIO.

The McKinley-Darragh company is planning to install 10 additional stamps in its mill to handle the increased output from the mine. The present stamp duty in the mill is four tons per 24 hours.—The Paymaster mine opened a 6-in. vein of cobalt on the 115-ft. level 150 ft. north of the shaft.—The O'Brien mill at Cobalt has been completed and 10 stamps in the concentration and sampling department have been started. The 30 stamps run in connection with the cyanide portion of the mill will probably be started about the first of September.—The shaft at the Ophir mine in South Coleman cut a 4-in. vein of native silver at a depth of 75 ft.—A 6-in. vein assaying 4500 oz. silver per ton was opened by surface trenching on the Nipissing property.—The Silver Cliff company shipped two cars of 600-oz. ore from its mine at Cross Lake. The company is having plans drawn for a 100-ton concentration plant to be erected at the mine in the near future. The company will resume sinking about the first of September.—About 200 ft. from the Foster boundary on the Lawson property a 20-in. vein of calcite and silver ore has been opened that is equal on the surface to the famous silver sidewalk. The average assay across the 20 in. is 3900 oz. silver per ton.—The Trethewey company has made the preliminary survey for a 30-stamp mill and concentration plant.

MEXICO.

GUERRERO.

A smelter with a capacity of 100 tons per 24 hours is in course of erection on the property of the Maine-Nebraska Mining Co., 1½ miles from Balsas. The company has obtained the concession of a water-power that will develop 100,000 hp., from the Mexican Government.

MEXICO.

Valentine Eleoro & Co. has installed a 10-stamp mill, re-grinding plant, and Pachuca tanks for cyaniding at their San Antonio mine near Temascaltepec.

OAXACA.

The Victoria Tapada is installing a cyanide plant at its mill.

SONORA.

The third shipment from the El Tremblor mine in the El Tigre district, amounting to six tons, is being sent to the railroad. On the two previous shipments the ore averaged \$330 per ton. The property is owned by N. D. Shippy and James Taylor.

TEPIC.

Waldo G. Myers is to install a complete milling and cyanide plant on his Zapote mine near El Lisco. There is an excellent water-right held in connection with the mine that will furnish ample power for all power purposes.

ZACATECAS.

Vasquez Mercado and Francisco Ortega have purchased the tailing dumps near Villa de Guadalupe for a European corporation. There is estimated to be from 3,000,000 to 4,000,000 tons of tailing in these dumps.

mining companies have made distributions reaching a total of £4,542,494. The greatest amounts paid were the following: East Rand Proprietary, £449,179; Robinson, £412,000; Simmer & Jack, £300,000; Ferreira, £142,500 and a bonus of £190,000. The dividends aggregate for the whole of last year, £8,569,916. Gold-mining companies outside of the Rand only declared £50,201 in dividends for the half year. More pitiable is the showing of the coal-mining industry. The Transvaal turns out about 3½ million tons of coal per annum, mostly for use on the Rand, and yet the coal mines' dividends total for the half year only £46,000, distributed by three out of about 30 collieries. Efforts made to establish a combination among the coal-producing concerns have not borne fruit. The value realized at the pit-mouth is now only \$1.20 per ton, though standing at \$1.80 per ton five years ago.

The death of Wager Bradford, manager for the Robinson Gold Mining Co., has caused universal regret. The deceased, one of the leading American engineers on the Rand, was born at Stockton, California, in 1863, graduated at Hamilton College in 1885, took a post-graduate mining course at the University of California, and came to the Transvaal in 1896. He has been manager of the Buffelsdoorn Estate and of the Langlaagte Deep (Rand Mines Group) since 1897. Early this year he assumed control of the Rand's premier mine, the Robinson. Mr. Bradford was a vice-president of the Chemical, Metallurgical & Mining Society, and took a leading part in public life, scientific and social, in Johannesburg. His body will be embalmed for interment in California.

The valedictory address of E. J. Laschinger, retiring president of the South African Association of Engineers, was full of good points. He dwelt convincingly upon the importance of recognizing the difference between 'efficiency' and 'effectiveness of method,' and contended that the economies which had been witnessed on the Rand of late were due to a study of both these factors. There still remains room for "vast improvement in the efficiency of labor." A thoroughly practical suggestion thrown out was that of organizing a staff or staffs of specialists, unfettered by routine duties, to investigate the problems of working-efficiency as they arise, and elaborate the details for the benefit of the industry.

The June output showed a decrease of 7270 oz. as compared with the longer month of May. The declaration of £2,621,818 for the Transvaal brings the total for the half year up to £15,447,500. There was no change in the stamp-position in June, the Rand total being 9140 stamps. Native labor returns continue to show the wastage characteristic of the present winter months. There were 8335 natives distributed, and 12,354 'boys' left as time expired, resulting in a wastage of 4019 'boys' for the month. This follows the May loss of 4622 Kaffirs. There still remain over 5000 Chinamen to be repatriated.

ROSSLAND, BRITISH COLUMBIA.

Le Roi Resuming Work — Centre Star. — Phoenix. — French Investments. — Fern Mine.

A small crew of men have been put to work at the Le Roi mine making preparations for the resumption of operations at that property. As has already been stated, development will be the chief feature of operations at the Le Roi for some time. A special fund of about two million dollars has been raised and within a few days the initial work will begin. Part of the plan is to explore from the 1650-ft. level to the 2650, in the most likely region of the mine with a diamond-drill. Ore shipments from the Centre Star Consolidated group during the week ending July 24, made a new record for the year, 4680 tons, exceeding the week ending May 1 (4280 tons) by 400 tons. The lowest shipments this year from the Centre Star were for the week ending January 9, 2950 tons. The activity at the Centre Star group here is making things hum at the Trail smelter of the Consolidated company down the hill. The value of the gross output of the smelter for the last month for which the figures are available was over \$800,000. Each month the refinery ships over 200,000 oz.

of silver to China. This metal is made 0.999 fine at Trail and is used for coinage. The Ottawa mint has been supplied from here with 250,000 oz. gold, for coins. The future looks bright for this plant, which was built by F. Augustus Heinze in the early days of the district (1896).

The mines of Phoenix have shipped over half a million tons of copper-gold ore already this year. While this is something less than was shipped to this date last year, it is stated that the grade of the ore is higher, and the way things point now conditions are favorable for exceeding the tonnage of last year to quite an extent. Boundary ore yields about 24 lb. copper per ton so that the recovery has been about 12,000,000 lb. Both the Granby and B. C. Copper companies are producing a good grade of converted crude copper and are laying it down in New York at approximately 10c. per pound. At some periods the figures have run as low as 8c. per lb., but this cannot be counted on, although there is little doubt that this figure will be reached in the Boundary in time. Things are getting into working form at the property of the B. C. Copper Co. Ore is being taken out, and a good crew is at work, although the force is far from complete. As yet smelting has not been resumed at the Greenwood plant. The shipments from the Snowshoe are being increased. The ore is being sent to Trail. Considerable surface work is being done. It is reported that the deal for the Nickel Plate at Hedley has been consummated, and that extensive work is likely to be started soon.

French capitalists who are interested in the big Blue Bell mine have been visiting the district during the past week. It is announced that French capital is being attracted by British Columbia, and that considerable Parisian money will find its way to meritorious local mines in the future. There are a number of metal and coal mines in this district now which are financed by Frenchmen. The old Fern gold mine has been re-opened and will be worked on a goodly scale. A 3-ft. vein of galena ore has been opened in the lower levels of the Westmount. About 20 men are now working at the mine. Auriferous gravel yielding \$10 to \$15 to the pan has been found in Summit creek. Work has been resumed at the McAllister mine, Three Forks, a promising silver property.

Frederic Keffer, consulting engineer for the B. C. Copper Co., has been examining some of the more promising mines in Kamloops district. On the strength of his report it is likely that the company will do development with the diamond-drill. This concern is pursuing an expansive policy, as is the Granby and the Consolidated of Canada. A railway is now being run to the Wellington and Central camp mines of the B. C. Copper Co., which will at the same time give an outlet for dozens of other properties yet in the growing stage. After three years of prospecting the owner of the Brown-Bulldog property, near Princeton, has opened up a 35-ft. lead assaying 5% copper, 14% zinc, 8 oz. silver, and \$8 gold. The ore is self-fluxing and the facilities for loading it on the cars at the railway near-by are good.

The Ikeda (Japanese) copper mine, Queen Charlotte Island, has been bonded to an English syndicate for \$200,000, for a period of two months. The group has so far proved rich in copper and gold; the ore fluxes easily, and transportation facilities are ideal. Quite an amount of American capital is coming into Nelson district of late, the acquisition of the Highland-Buckeye, Lucky Jim, and other silver-lead and gold mines, being examples.

BUTTE, MONTANA.

Rich Discoveries. — High Ore Mine. — Elm Orlu. — Gagnon — La France Co. — Electric Power. — Sierra Consolidated Mines Company.

John D. Ryan's faith in the copper mines of Butte, and his extreme optimism regarding their future is being justified by improved conditions in the mines of the Amalgamated Copper Co., the North Butte, Butte Coalition, and other properties. The recent strike on the 2800-ft. level of the High Ore mine of the Anaconda Mining Co. is of importance. It is the deepest point at which mining is being done in the Butte district, the next deepest being on the 2400-ft. level of the Anaconda mine. The High Ore is 600 ft. deeper

than the Speculator shaft of the North Butte company. It is significant that on the next level above the 2800-ft. in the High Ore the vein was comparatively lean, but on the new level the vein opened rich again, and some of the finest looking copper glance ever seen at the Washoe smelter is being shipped. The discovery repeats the history of Butte mining, rich levels being found after an experience of several poor ones. It is expected that by the latter part of October the Jessie vein will be cut on the 2200-ft. level. By the first of the year the Granite Mountain shaft will be completed down to the 1600-ft. level, and will be put into commission as a second working shaft, when the production will be increased fully 100%. Connections are being made with the shaft from three levels, and other development is being carried on, including the extension of the 2200-ft. cross-cut, and another cross-cut on the 1800-ft. level to the Berlin group.

The new level being opened by the Butte Coalition on the 1700-ft. levels of the Tramway shaft into the Minnie Healy ground has opened several new veins of remarkable richness. Without attempting to push the production of the Butte Coalition the ore output has been gradually increasing, due chiefly to the opening of several new veins and new levels. The Rarus and Minnie Healy mines are now yielding about 1600 tons of ore per day, of a somewhat lower grade than formerly, more of the second-class ore being shipped.

In the Little Mina, diamond-drilling, done for the purpose of opening a drainage into an adjoining mine, has disclosed a continuation of the good ore in the vein to a depth of 1700 ft., or 600 ft. deeper than the present lowest level. Work on the Parrot mine continues without producing sensational results. The vein is being opened on the two lower levels, and while the ore is of a low grade, conditions are not discouraging, and the mine is yielding its usual quota of ore, about 400 tons per day.

In the Elm Orlu mine, owned by W. A. Clark, a tremendously rich vein has been opened on the 1200-ft. level, and several hundred tons of ore are shipped daily. The Elm Orlu ore runs 12% copper and is unusually high in silver. The vein is said to extend under the Pilot claim, owned by the Pilot-Butte company, which latter company has not been operating since the financial slump of 1907. Adjoining the Elm Orlu on the east are the properties of the Butte & Superior Copper Co., which is opening good copper orebodies on the 1200 and 1400-ft. levels. The Butte & Superior has in the Blackrock an immense body of zinc ore, from which regular shipments are now being made at a profit to the company. The Tuolumne Copper Co. is winning gratifying results. Its claim is situated near the Speculator of the North Butte company. It is opening the 1400-ft. level. The vein on the 1000-ft. level is about 20 ft. wide.

The Gagnon on the new level is developing practically a new mine for the Trenton Copper Co., an Amalgamated subsidiary, and it is not unlikely that the Trenton will, before long, become a dividend payer again. The property was a keen disappointment to the Amalgamated people when they found what had been acquired, but development was pushed, and after sinking the shaft several hundred feet deeper a new orebody was uncovered. So satisfactory has the development been that the company has concluded to sink a new working shaft in place of the old incline shaft.

Operations may soon be resumed at the Lexington mine by La France Copper Co. At the recent meeting of stockholders it was stated that La France company was again unable to meet its July coupons on bonds, and that the United Copper Co. would probably issue its notes at 6% again, as it did last year. La France company has not yet been able to raise money with which to redeem its property, which was sold two years ago for about \$5000 delinquent taxes, but it has paid the tax for 1908. The new directors of La France are: W. A. Kidney, R. A. Carnochan, David Gilbert, and E. M. Brennan, of Butte, and John T. Williams, of New York.

Work has been started on the construction of the electric wire line from Great Falls to Butte, by means of which electric power is to be conveyed to the Butte mines from

the two great power-dams now being erected on the Missouri river by John D. Ryan and associates. As soon as the line is completed it is anticipated that the power-plant will be completed. Then electric power will replace steam-power in all the mines of the Amalgamated Copper Co., the North Butte, and Butte Coalition, in the Butte district. Few changes at the plants will be necessary for the substitution, and the steam plants will be kept in reserve as auxiliaries.

The Cole-Ryan people have made a new flotation of a Mexican gold property. The company is known as the Sierra Consolidated Mines Co., with a capital of \$5,000,000, divided into 500,000 shares, of which 300,000 shares are to be issued to pay for the property and provide a working capital of \$1,520,000, on the payment of \$10 per share. At present only \$6 per share will be called for. The properties, consisting of both mineral and timber land, and a number of old producing mines, comprises 60,000 acres situated in the Ocampo district of western Chihuahua.

SALT LAKE, UTAH.

Tintic Smelter Resumes.—Copper Output of Utah.—Ohio Copper not Bought.—Fink Smelter Abandoned.—Uncle Sam Dividend.

D. Lester Mangum, general manager of the Tintic Smelting Co., has notified shippers that they can resume shipments. The smelter has rekindled its fires in three of the lead furnaces, and will have these running at full capacity by Wednesday. All repairs and the overhauling of the entire plant have been completed. New blowers of larger capacity have been put in, the sintering plant has been changed, and the big reservoir is filled to the brim. A trial has been made of every department and the results are reported to have been highly satisfactory. The fourth lead furnace will soon be blown in, and finally the copper furnace. This will give the plant a capacity of 900 tons of lead ore and 225 tons of copper ore daily. An inventory of the ore and bullion on hand at the time of the shut-down has been made, and it is learned that the smelter has made a small profit on its operations for nine months. This has resulted in a determination on the part of the Knights, the principal owners, to continue the plant, and a bid will be made for all ores coming into this market. When Jesse Knight decided to build this smelter he promised the shippers that he would keep the plant in operation steadily. Several attempts have been made to purchase the smelting plant, and the Iron Blossom and the Colorado mines, all owned by the Knights. In so far as the Cole-Ryan interests were concerned all things were agreed upon with the exception that they would not agree to make the Tintic smelter a permanent plant. The Knights would not agree to a sale unless these furnaces were to run, and now the Knights have concluded that as long as there is a profit to be made in the smelting business they will not sell. The representative of the Cole-Ryan interests has just left the city and announced the deal as off.

The copper output in Utah for July shows approximately 11,000,000 lb. delivered to the Garfield smelting plant. Of this the Utah Copper Co. supplied about one-half; Boston Con. is next with over 2,000,000 lb. An estimate of the profits on the production is placed at \$500,000. From a State that produced scarcely any copper a couple of years ago, Utah is now taking high rank. With July as a basis, 132,000,000 lb. of copper are now being produced by the mines of this State annually on which there is a profit of \$6,000,000 per year at the prevailing market prices. With improvements now under way in the milling plants, and the mines that are scheduled to come in with a large tonnage of copper, this output will be doubled within the next two years.

There seems to be no ground for the report of the purchase of the Ohio Copper by Cole-Ryan people. While a considerable amount of money has been raised to pay off the floating indebtedness of the Ohio, it seems to have been obtained from another source. The steel structural work for the trestle has not arrived, and in the meantime the second unit of the mill is being completed; this is to be

followed by construction of the third section. Colin McIntosh, the general manager, says that they will have the mill running within 60 days. Samuel Newhouse and Edward Fink could not agree upon the formation of a company to take over the Fink patents on the new smelting process, and the plant is idle. Mr. Fink has returned to his home in the East, and Mr. Newhouse will carry on no further operations, unless some adjustment of the existing differences can be patched up. There is great disappointment over this turn in the affairs of the new smelter.

A dividend of 10c. per share, aggregating \$10,000, has been posted by the Uncle Sam Consolidated Mining Co. A dividend has also been declared by the Iron Blossom, of 8c. per share, amounting to \$79,200; by the Colorado, 8c. per share, aggregating \$80,000; and the Sioux Con., of 7c. amounting to \$52,457. All these are Tintic producers.

LOS ANGELES.

Mile Deep Hole of Union Oil Co.—Developments Around Piru, Ventura County.—Lower California.

The deepest hole in California and the deepest producing oil-well in the world has just been completed by the Union Oil Co. on their Brashear lease, in the Salt Lake field, seven miles west of Los Angeles. It is known as Brashear No. 1 and is 5323 ft. deep, or 43 ft. more than a mile. This well was begun in March, 1907, and drilling operations have been going on continuously ever since, that is, for a period of two years and five months. The total cost of the well has been roughly \$40,000. An ordinary standard rig was used and no unusual conditions were met in the drilling, nor were any innovations attempted in manipulating the tools or cables. It was just straight drilling. The usual care displayed by the drillers of the company enabled them to attain the great depth. Manila cable was used to a depth of 1000 ft., and after this a steel cable. The formations drilled through were conducive to successful operation, being largely brown shale, which stands up well ahead of the casing. The log of the well is as follows:

| | To feet. |
|---|----------|
| Soil, sand, and gravel (the superficial formation over the whole Salt Lake field; traces of tar at 100 ft.) | 100 |
| Brown shale | 240 |
| Tar sand | 250 |
| Brown shale | 2,792 |
| Rich oil sand..... | 2,795 |

| Brown shale | 5,323 |

Some record strings of casing are used in the well, as follows: 100 ft. of 15-in., 1048 of 12½, 2900 of 10, 3908 of 8¼, 5323 of 6½. A pump was installed in the hole at 3300 ft. from the top, and enough oil came through the intervening 2000 ft. of water from the oil sand at the bottom to partly fill the sump on a trial pumping test. The pump is now being lowered 1000 ft., and it is the belief of the officials of the company that with but a thousand feet of water to penetrate, the oil will rise in quantities sufficient to pay to operate. It takes nine minutes to raise the tools from the bottom of the well.

Until the completion of Brashear No. 1, the well of the Los Alamos Oil & Development Co. in the Lompoc field, Santa Barbara county, which is over 4400 ft. deep, was the deepest producing well in the world. This well, which until very recently produced 30 bbl. or so of light oil, together with considerable quantities of water, has lately stopped producing water and has increased the yield of oil between 300 and 400 bbl. per day. It is a wonderful well considering the difficulties of manipulation at such great depths. Another deep well which is attracting considerable attention is that of the Santa Fé Railroad company in the Kern River field, which is now down over 4230 ft. It is believed to be below the oil sands of this region and will probably be abandoned without obtaining any positive results.

Little development work is being done in the fields about

Piru, Ventura county, although several old properties like the Torrey, Eureka, Sunset, Fortuna and Modelo are operating wells drilled several years ago. The permanency of the wells in this part of the State is wonderful, many of the holes producing nearly as much oil after a lapse of eight or ten years as they did after a lapse of a year or so following their completion. The fall-off in production is quite rapid, usually about 75% in the first 90 days, but after this time the rate of decrease is very much less. The Harris Oil company, operating between the Modelo and Sunset groups, is drilling some new holes with more or less success, and the Couch well, in Torrey canyon, one-half mile below the Union's wells in the same canyon, is just being finished up with something less than 100 ft. of oil-sand in a hole less than 500 ft. deep. This last well proves considerable new territory north of the Torrey group.

Concerning the prospects for oil development in Lower

Brashear Well, A Mile Deep.

California, W. W. Orcutt, chief geologist of the Union Oil Co. tells of an experience he had in examining an 'oil seepage' near Ensenada. The parties who were showing him the prospects took him along the top of the sea-cliff for several miles, and finally, arriving at a particularly precipitous part of the bluff, triumphantly pointed to some black streaks apparently emanating from below small overhanging blocks of the white stratified volcanic ash of which the cliffs were composed. The streaks certainly looked like tar seepages, so after a hazardous climb, the inquisitive geologist arrived at one of them, when to his surprise he saw the seepage gradually melt away into a swarm of buzzing black flies. These flies, like the native inhabitants of the country, wished to rest in the shade, and sought the only available places, the small overhanging ledges of the sea-cliff. Thus do the hopes of the oil man often take wing.

KALGOORLIE, WESTERN AUSTRALIA.

Recent Developments.—Meeting of Australian Institute —Geological Features of Kalgoorlie.—Tailing Disposal.—Statistics of Production.

What with numerous developments from one end of the field to another, two discoveries of tin, and the visit of the members of the Australian Institute of Mining Engineers, this has been an interesting month. At the north end of the belt there have been fair developments in the Golden Link; then the Kalgurli is down now to 1700 ft., and is erecting a new hoist for deeper work; in the Per-

severence upper-levels some promising discoveries have been made; work at 1970 ft. in the Ivanhoe is revealing plenty of ore of better value; while at 2000 ft. in the Horseshoe, the east branch of the No. 3 lode is 18 ft. wide, worth \$22 per ton, these being free gold and telluride ores from wall to wall.

Two discoveries of tin were made, one in the northwest fields, and the other some 12 miles from Coolgardie. Not much work has been done on the latter find, but assays return up to 67% Sn; while some tantalite is also present, giving 45% tantalic oxide, rather low-grade as compared with the stibis-tantalite found with tin in the Green-bushes field in the southwest.

An extraordinary return comes from the Nemesis mine at Yuckanana, 60 tons from a depth of 250-ft. giving gold worth \$24,000.

During the year 1908 the Kalgoorlie Electric Power & Lighting Co., which supplies many of the mines, tramways, and other enterprises, with power, made a profit of \$105,000. After paying interest on debentures, dividends on preferred and ordinary shares, dividend duty, depreciation and renewals, \$6000 was carried forward. Preferred shares were paid at the rate of 6%, and ordinary shares 4% per annum. In May, 1901, the Australasian Institute of Mining Engineers visited this centre; and during the past week the members paid another visit. These consisted of many mining men from all of the Eastern States of Australia, and also a number of students from the several Schools of Mines in the East, it being the custom of the Institute to give prizes to the students who write the best papers on the trip, or on the mining and metallurgic work in the district visited. Had there been no labor troubles in Broken Hill, and no depression in Tasmania and other centres, many more visitors would have come. The local committee at Kalgoorlie had made all arrangements for the comfort and interest of the members, and everything passed off well. On May 26, at 8 p. m., the Presidential speech was delivered by R. Hamilton, manager of the Great Boulder Proprietary, and a conversation was also held. This meeting was held in one of the lecture rooms of the School of Mines. Mr. Hamilton's interesting address was more in the form of a lecture. He traced the history of the Kalgoorlie field from its beginning; the new ores that puzzled the prospectors; the types of lodes, and the reason why so many remained so long undiscovered; the methods of mining; prospecting by diamond-drill; the two principal processes of treatment in vogue; and some interesting statistics in conclusion. The lecture was made more interesting by blackboard diagrams, especially in connection with diamond-drilling. Mr. Hamilton has had much experience in that work, and he stated that horizontal holes were more reliable than those put in at a depressed angle, the drill always tending to run at right angles to the dip of the country; he had not yet solved this peculiarity of the drill. The President then introduced Mr. Adams, who read a paper on 'The Disposal of Residue in Kalgoorlie.' This was of interest as it contained new data on the sluicing system of dealing with the residue from filter-presses alone; presses and vacuum together; and from the vacuum process alone. The writer dealt with the pumps, pipe-lines, dams, and detailed costs. H. Gregory, the Minister of Mines, dealt in a clear manner with the subject of Technical Education under the Mines Department, and with mining generally.

In the lecture hall of the School of Mines museum on May 27, about 120 mining men listened for 2½ hours to a lecture on 'The Geology of the Kalgoorlie Field, with Special Reference to the Orebodies', by Mr. Larcombe, the instructor of Geology and Mining at the School. It was a brilliant lecture. He commenced with a resumé of the geology of Western Australia, showing slides, sketch maps of the Golden Mile, and others; a section from east to west; and microscopic views of rock-sections thrown on a screen. Mr. Larcombe is preparing a geological report on the Kalgoorlie field, which will be published by the end of the current year.

On May 28, in the museum lecture hall, a most interesting evening was spent. The State Mining Engineer,

Mr. Montgomery, read a paper entitled 'Some Geological Considerations Affecting Western Australian Ore Deposits'. He dealt at length with the geological conditions in the State. Western Australia was beneath the sea within recent geological times, the salt water found locally was due to this fact. The extra richness in the oxidized portions of the lodes was due to secondary enrichment, and as work proceeds in depth the fineness of the gold is lower. In places the granite intruded the diorite. Mr. Hamilton wished to know what had become of the debris from the mountain chains, also the likelihood of the conglomerates around Kalgoorlie carrying gold. J. Malcolm MacLaren stated his conception of the formation of the lodes here. He did not think that Western Australia had been under the sea, as there were no marine fossils, and the arid country would account for the salty nature of the water. He contended that the diorite intruded the granite. Mr. Larcombe then gave his idea of the formation of the lodes in this field. He was not of the 'intrusive' school. The great Brownhill-Iron Duke-Oroya shoot was the result of great fault-planes, while the other lodes were formed by the rock coming up from some deep-seated origin.

The State Geologist, Gibb Maitland, dealt exhaustively with the rocks of Western Australia, more especially those of the northwest fields. He explained these on his new geological maps of Western Australia and Australia, now in press. In his remarks he said that all mine-plans should have geological records marked, and instanced cases in Victoria where the plans and note-books of many mines had been wilfully destroyed. Mr. Montgomery replied shortly, arguing that the question of debris from mountain chains was not so difficult to answer, and that the wide depressions on the fields held a great deal. The conglomerates or boulder beds out of Kalgoorlie he had not examined closely. Marine fossils had been found, although few. As to the granite, he contended that there were two or three kinds in Western Australia. The visitors spent a day in Coolgardie, and on the 30th went by special train up the Rurrawang line to inspect the fuel industry for the field; and the next day the party left for Perth, bound for the Eastern States.

Mr. Hamilton's address concluded by giving some interesting figures: Of \$400,000,000 gold from Western Australia since 1886, Kalgoorlie has yielded \$210,000,000; of \$94,000,000 dividends in that time, Kalgoorlie has paid \$72,000,000; in 1908 the local mines (Kalgoorlie) paid \$6,000,000 in dividends; \$6,000,000 in wages; \$500,000 in general expenses; and \$300,000 in dividend duty. With reference to the latter item, it may be explained that an Act of Parliament was passed in 1902, to levy a duty on companies operating in Western Australia. On companies operating only in Western Australia a tax of 5%, or 24 cents in \$4.80, on the amount or value of dividend paid; and on companies operating in Western Australia and elsewhere, a tax of 5% on dividends paid from the Western Australia business only.

The following were the May returns:

| Name. | Tonnage. | Yield. | Profit. | Dividend. |

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Ammonia in cyanide solutions is not easy to determine. No simple methods, suitable for routine laboratory use, have been evolved. It can only be done by elaborate analytical methods.

Boro-silicates exist in nature, and may easily be formed when boric acid is fused with metallic oxides, in the presence of oxides of the alkaline earths. Borax when fused with metallic oxides forms double soda-metallic borates, which are extremely fluid, but there is no certainty that the bi-borate of soda is dissociated so as to admit of the formation of silicates. Silica cannot be fused with borax below the temperature for fusion of the silica alone.

Carbonic acid gas is found in large quantity in many mines. When a person is overcome from this gas resuscitation can be brought about by artificial respiration, conducted as in cases of drowning, with the application of ammonia or ether, or vapor of hot-water. As soon as the patient can do so he should be made to drink strong coffee. Camphor in $\frac{1}{2}$ -grain doses may also be administered. Ordinary rhinitis tablets are efficient.

Strontium was not among the mineral products of the United States for 1908. The principal market at present for strontium in the form of the carbonate (strontianite) is in Germany, where it is used in sugar refining. It would be largely employed in the same way by American sugar refiners if it could be had at sufficiently low prices. It is probable that at \$10 per ton delivered it could command a market. Aside from its use in the purification of sugar its only employment is in the manufacture of fireworks, the carmine-fire being produced by burning a mixture of strontium salts with suitable combustibles and sodium nitrate.

Quartz, or flint, as it is termed commercially, is used for wood-filler, pottery, paints, and scouring soaps. It prevents shrinkage in burning pottery. It is also used in glazes. Suitable quartz should contain less than 0.5% of Fe_2O_3 . In paints it helps to resist the effect of the weather. A growing use for quartz of exceptional purity is in making quartz-glass, which is merely fused silica, out of which chemical apparatus is made that has the advantage of not being subject to breakage from expansion or contraction. It is also in some demand for lining copper converters and bessemer steel converters. The total demand is small, sales in 1908 being, crude quartz 23,505 tons, worth \$32,443, and ground silica, 15,320 tons, valued at \$106,203.

Concentration of iron-ore is becoming an important industry in many of the Eastern States and Canada, and is also extensively practised in Norway and Sweden. Both wet methods and dry (magnetic) are employed. In one magnetic system also the pulverized ore is mixed with an excess of water

and caused to flow underneath the poles of a strong electro-magnet, the particles of magnetite being lifted out of the wet pulp. This method is said to avoid the difficulty of carrying gangue over with the concentrate in 'nests' formed under the influence of the lines of magnetic force. Iron-ore concentrate is rendered amenable to blast-furnace smelting by 'nodulizing', which consists in agglomeration in revolving kilns fired with coal-dust, as is done in burning cement. It makes nodules similar to modern rotary-kiln cement-clinker.

Effects of phosphorus, silica, manganese, and other substances in the manufacture of pig-iron are so many and complicated that no resumé can attempt to give much valuable information. The phosphorus of the ore re-appears in the pig-iron, and can be eliminated in steel making only by means of the basic-lined converter, which is little used, or by the basic open-hearth process. Good elimination of phosphorus can in that way be obtained, and the phosphatic slag then becomes a valuable by-product available as a fertilizer. An attempt to discuss the behavior of silica is quite impossible in brief space. No limit can be set as to the amount of SiO_2 that might be accepted in an iron-ore, that depending on its other ingredients, and the local demand. Quotations on ores can be had from iron smelters at Pittsburgh, Cleveland, Chicago, and other points.

Fine jigs, when working improperly, may be brought into form by several adjustments. First look to the hutch; it may have become filled by the breaking of the screen. If the hutch proves to be in good order, the screen should next be investigated, and if 'scratching' does not remedy it, the bed may have to be shoveled off and the screen beaten with an old piece of belting, to clean the meshes and overcome the 'blindness'. The trouble may be from an increase of feed and overloading, requiring more water under the screen. Decreasing or increasing the height of the tailboards are changes of a permanent character which are often found necessary in new mills, lowering the height having, of course, the effect of decreasing the bed and lightening the load, making the jig more 'lively' in its action. If the jig still works improperly, the stroke of the plunger may need adjusting, or the speed may be changed. The length of the plunger-rod has an effect often underestimated, as has also the depth of the dividing board between the plunger and screen compartments. Fine jigs, especially those treating a product less than 5 mm. diam., must generally be bedded by a coarser product, in order to make a good hutch-product. The product through a 3-mm. trommel screen, if properly classified, may be treated on an 8-mesh wire screen, or on a 3-mm. punched screen, and make a satisfactory concentrate in the hutch. The ratio of the size of the bedding material to the size of the feed is generally about 3 to 1, or in other words, a thin bed of concentrate from an 8 or 10-mm. jig makes a satisfactory bed for a 3-mm. jig. This bed, especially if of galena, requires frequent renewing, as the abrasion soon reduces the size of the particles, the abraded material passing into the hutch.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Theory of the Settlement of Slime.

The Editor:

Sir—Harrison Everett Ashley's paper which appeared in the MINING AND SCIENTIFIC PRESS, June 12, 1909, forms a valuable contribution to the discussion on the settlement of slime, inasmuch as it leads us to a consideration of what slime really is. Incidentally, Mr. Ashley's paper calls for an explanation of why viscosity was not specifically mentioned in former contributions on the subject. This important factor was, it is admitted, rather crudely set aside with the remark, "pulp must not be confounded with liquid medium," in the hope, now justified, that this phase of the question of the physics of slime would be introduced by a more competent authority. In connection with this question of viscosity, which is the measure of the internal friction of a fluid, the following considerations are suggested: the 'sol' form of matter may be considered to be a semi-solution. The absorbent gelatinous envelope constituting the 'gel' form, under the favorable conditions named, breaks up, so to speak, and a condition of matter is formed which is not a true solution, being as Mr. Ashley states, a turbid suspension, but which nevertheless approximates closely to the condition of solution. The greater the turbidity the greater, it is reasonable to assume, is the viscosity of the semi-fluid. The addition of acid has the effect of destroying this condition, and of precipitating solid matter from the medium, thereby, as far as the medium is concerned, taken as a whole, reducing its viscosity.

Now, when we come to the last paragraph of Mr. Ashley's article, we find that in dense clay slips, in which the sol form of matter has been created, the addition of acid tends to stiffen the slip as a whole, in other words, to increase its viscosity. Herein would appear to be a paradox, for the explanation of which we return to the definition of viscosity.

Viscosity is the measure of the internal friction of a fluid. Within the meaning of this definition, can a composite mass of solid and liquid be considered as a fluid? Let us take Mr. Ashley's thin pulp. The gel exists upon crystal grains. When water is added the turbid suspension is formed which will not settle. The crystal grains, however, are left in addition. Upon precipitation of the gel form of the colloid, the viscosity of the medium is reduced.

In the case, however, of a dense clay slip, although the same effect is produced in the medium itself by the addition of the acid the result is, that in a composite pulp-mass, already containing a high percentage of solid material, a still further addition of solid matter is created, which in effect, by increasing the concentration, stiffens the slip, but cannot be said to have increased the viscosity of the medium. To take a hypothetical example: supposing a pulp to be

made up of a high percentage of solid slime in a solution of barium chloride; sulphuric acid is added; further solid matter is created as barium sulphate; and thus the ratio of solids to liquids is increased in the mass. Taking Fig. 4 in my previous contribution as an example, is not this contention borne out? We see that in each case, with the exception of the very thin and very heavy pulps, the addition of sulphuric acid assisted settlement at the start by reducing the viscosity of the medium and throwing down the gel form of the colloid, but in each instance we notice a perceptible increase in retardation as the solids settle as compared with the settlement of the same pulps where no electrolyte was used. In this figure, 1 a and 1 b, 2 a and 2 b would certainly appear to be in accordance with Mr. Ashley's explanation, but 8 a, 8 b, and 8 c are still stronger arguments pointing to the mistake of considering a slime-pulp in the light of a medium. In slime settlement one has to consider

the differentiation of the solid and liquid components of a pulp-mass, and it is this differentiation which would appear to preclude the possibility of accepting viscosity of medium as a prime factor in the question of settlement. In other words, the criteria affecting viscosity of clay slips and settlement of slime from slime-pulps are not identical. A clay slip is poured more readily by preventing the precipitation of the colloid. A slime is settled by stiffening the pulp. We are thus brought to the consideration of what it is that constitutes a slime from the point of view of the metallurgist, and in attempting any definition it will be at once seen that the viscosity of the medium is an all important factor. The following dual classification of slime is tentatively submitted: (1) In connection with concentration practice: slime is solid matter in such a fine state of sub-division that the viscosity of a medium in which it is suspended is able to retard the velocity of its settlement by imparting to it a virtual specific gravity less than normal.

(2) With relation to cyanide practice: 'slime' expresses a condition of finely divided solid matter by virtue of which a sufficient amount of friction is set up with a liquid surrounding it to reduce the relative mobility of the solid and liquid particles below the economic demands of settlement or percolation.

In regard to settlement of slime it may be said that whether the force opposed to gravity be due more to viscosity of medium or to electro-static repulsion, retardation of settlement clearly follows

accumulation or concentration, and thus it is seen that the settlement of slime may be assisted by obviating this accumulation, in the way of removing slime, as it settles, from the bottom of a settling tank.

HORACE G. NICHOLS.

Continuous Revolving Slime Filter.

The Editor:

Sir—An editorial note in your issue of July 10 referring to the utilization of the continuous revolving filter in South Africa states that this system was first introduced into American practice by Bertram Hunt only a year ago, and further, “it is pleasing to note this recognition of a meritorious innovation in cyanide work.” I desire to claim a share in the suggestion of what you are good enough to denominate a “meritorious innovation in cyanide work,” and believe that I am justified in claiming to have proposed the first continuous revolving filter for which letters patent were issued to me in 1905. The device was described in the MINING AND SCIENTIFIC PRESS of February 9, 1907, and was the first, so far as I am aware, to provide, among other things, for a continuous flow of pulp on to a horizontally moving filter medium, immediately beneath which was a plurality of compartments, the whole revolving around a central valve so arranged that the compartments were under the influence of vacuum during the greater part of the revolution and afterward were brought into communication with compressed air or air at normal pressure under which the cake was scraped off by means of a stationary scraper, the cleaned filter then passing immediately under a fresh charge of pulp.

Duties of another character on the Eastern coast have so fully occupied my time that active operations looking toward the manufacture and sale of the machine have been delayed, arrangements have been perfected, however, by which it is expected that it will be now put upon the market.

EDWARD PARRISH.

Newport, Rhode Island, August 5.

Abbreviating Code Messages.

The Editor:

Sir—I beg to submit to those who must waste their substance on code telegrams and code cablegrams, a method of reducing the number of words without abbreviating or fogging the message. This method of condensing can be used only with numbered codes. By the use of the following tabulation, or any other made up of two-letter pronounceable combinations, two numbers representing two phrases are made over into one word of 10 letters. Of course, where a code is compiled with words of only 5 letters each, this scheme is unnecessary, since two such words can be sent as one. If it is desired to change the tabulation given, the change should follow some system or regular sequence. This is because otherwise the translator of the message finds difficulty in placing the pairs of letters. Note that, with only one exception, in all the pairs of letters the vowel is first.

With this in mind, errors of transmission can be detected at a glance and corrections requested, without waiting to translate the message. A convenient way of writing and translating such cipher messages is shown. In sending, the phrases with their respective numbers are first written in columns. The cipher words are then added as constructed. It cannot be too forcibly urged that all such messages should be typewritten. The unfortunate operators have no means of deciphering poorly written words of such outlandish appearance.

MARK R. LAMB.

Milwaukee, Wisconsin, July 31.

Slime Concentration.

The Editor:

Sir—I have read with keen interest the subject of possible improvements in slime concentration contributed by ‘C.’ in your issue of August 7, and, thinking perhaps the experiments and results I obtained from a simple device for increasing the amount of mineral saved from Frue and Johnston belt-concentrators might be of value to all mill-owners, I request the opportunity of setting forth matter pertaining thereto.

This device is a clear-water distributor for belt-concentrators, designed to remedy the defects of distributors furnished by the manufacturers. It consists of an ordinary distributor-box of the size and shape usually found on vanners, but instead of having vertical channels or metal-launders for distributing the water I used a small brass valve of the pet-cock style, by some manufacturers termed ‘end-valves’, placing them equidistant on the face of the box, midway between the top and bottom, in the spaces formerly occupied by the channels. A tight and permanent insertion was made by boring the

holes $\frac{3}{32}$ in. smaller than the diameter of the threaded end. I then placed a strip of wood $\frac{1}{2}$ by 3 in. wide in the centre of the box the whole length of the box, recessed at each end, the bottom-edge inclined about 15° toward the face of the box, thus providing a partition, the bottom-edge being within $1\frac{1}{2}$ in. of the bottom of the box. At the end of the box opposite from the clear-water feed I placed a short $\frac{1}{4}$ -in. nipple, about 3 in. long, inserted in the back partition near the top, about 1 in. below the top. I also put on an ell and a short nipple on the outside end, leading downward into a small funnel, placed in the end of a $\frac{1}{2}$ -in. discharge pipe leading to the tailing launder, or to a sump-box, so that it could be returned to the clear-water tank to be re-used. I allowed a gap of 3 in. between the bottom of the nipple and the funnel, so that the overflow could be observed from all parts of the vanner floor.

The chief value of this device is an absolutely even pressure of water in all parts of the box, and the elimination of currents; also it equalizes any variation in the flow from the clear-water pipe-line. This is accomplished by allowing an excess of clear water to enter the box, feeding all the valves, no matter how wide they are open, and overflowing to the tailing. The value of the partition lies in clarifying the water, and freeing it from small chips or other debris, and by placing a small piece of 10-mesh screen vertically in the box close to the overflow, the debris will be drawn there and may be removed periodically. This arrangement may be placed on any vanner now in use without disturbing any piping or other devices, and once tried its value will be immediately recognized.

The first cost is greater than the other types of distributor-boxes, but the increased saving is apparent in the first 24 hours. It involves the purchase of a number of small end-valves, but the added carpenter work and small pipe-fitting labor can easily be accomplished by the average concentrator-hand during his spare time. Aprons may be placed on an incline below the box so that the flow may be let onto the belt, and these may be of any design suited to the pulp. Whether they are suspended close to the belt or somewhat higher makes no difference with the distributor box described. In adjusting an individual valve on this distributor it is not necessary to change any of the others to compensate for the increased or decreased flow from the valve so changed. Furthermore, in practice, I found that by setting the valve on the supply-pipe to flow an excess over the amount required for the tailing containing the maximum of mineral, thenceforward no change was required in the supply-valve, and in case of a shut-down or sudden stoppage of supply water, when the mill started up again, and the water again flowed, it was not necessary to go over the supply-valves and regulate them. Of course in some camps where clear water is at a premium there is a slight added expense for returning the excess of clear water, but this is offset by the value of a complete control of the clear water from the distributor, inasmuch as no excess of clear water reaches the belt.

Co-operative Topographic Surveys.

The Editor:

Sir—I am desirous of making some comment regarding the recently adopted policy of the United States Geological Survey in co-operative topographic surveys. The Geological Survey of New Jersey is not affected by this ruling, our co-operative topographic work having been completed about 1887, hence I have not the same personal interest in its application as some State geologists. As to the wisdom of adopting a definite policy there can, it seems to me, be no question. The authorities of each State can now determine with some degree of certainty how much money can be used in topographic work. The embarrassment heretofore caused by inability to use an entire appropriation after it had been secured from the Legislature on the basis of a 'dollar for dollar' co-operation will be removed. The State surveys can now estimate more accurately than before how much they can use in co-operative topographic work. This is certainly an advantage. As to whether the details of the policy adopted are the best possible, there may be difference of opinion, but it must be conceded that the Federal survey owes some topographic work to every State in the Union, irrespective of whether it is co-operating or not, and that the debt to the public-land States, where the Federal Government is a large land owner, is pressing. It would seem fair that in the distribution of topographic work in States which have no public lands, some advantage should be given those States which are ready to contribute to this survey, for in this way much more territory can be mapped for the same amount of Federal money, and the completion of the Atlas of the United States would be realized the sooner. I think, too, that it must be conceded that in distributing the funds available for co-operative work preference should be given to those States which have the smallest area surveyed, since it is apparently impossible to accept all the offers without change. It does not appear from the Director's statement whether non-co-operating States, having no public lands, will receive any allotment this year. If they do not, and this is a part of the policy to be followed in succeeding years, it can readily be believed that the new plan will not meet the approval of those State surveys.

HENRY B. KUEMMEL.

Trenton, New Jersey, July 12.

Taberg is a mountain in Smaaland, near the southern end of Lake Wetter, in Sweden. It is a classic locality for geologists on account of its remarkable deposit of magnetic iron ore, which is a segregation from a basic magma. The intrusive rock consists of magnetite, olivine, labradorite, and pyroxene. This rock is called hyperite. The segregation contains 31% metallic iron. Posepny disallowed the conclusion that the ore was a segregation, but most geologists now accept the theory of its formation as originally propounded by Toernebohm.

Each geological horizon has some distinctive lithologic character, showing that the main earth-changes have been due to world-wide causes.

ALL-SLIMING.

Written for the MINING AND SCIENTIFIC PRESS
By E. M. HAMILTON.

In articles on the cyanidation of silver ores one often reads statements to the effect that the finer the ore is ground the higher the extraction of silver, and that it is now generally admitted that the all-sliming method is the only one for silver ores. Such generalizations as these are, I believe, open to question. Doubtless there are ores in Mexico and elsewhere which need to be slimed in order to give the best commercial results, but in my experience they are in the minority. Even in cases where total sliming will yield the highest extraction it does not therefore follow that that method is commercially the best, and there are instances where even with all-sliming the extraction is no better than that obtained by a separation of sand of a suitable degree of fineness, followed by leaching and agitation respectively.

It is not the function of the metallurgist to transfer without question from the laboratory to the working plant theoretically perfect chemical methods, but rather to combine the qualities of the chemist with those of the man of business, and so to modify theoretical ideals as to obtain the best commercial result. At the present time 'all-sliming' is a common phrase among mining men, and yet, how many of its advocates are putting it into practice? I may here state that for the purposes of this article, I mean by 'slime' everything that will pass a No. 200-mesh laboratory screen. How many so-called all-sliming plants produce a pulp all of which will pass a No. 200-mesh screen? If there are any, it would be interesting to have some figures on the cost of production.

I know of two companies which had mills running on the all-sliming system where the sand coarser than No. 200-mesh amounted to 15 up to 20%. I know of another company running on the all-sliming system where the sand coarser than No. 200 reached 20 to 35%. Such work as this is not all-sliming. Moreover, I maintain that it is bad metallurgical practice, because it is an attempt to treat two different products jointly by a process suitable only to one of them. Even where the method of agitation is such as to admit of sand and slime being cyanided together without detriment to the machinery, it yet seems obvious that a treatment which will suffice for the slime, in point of time and cyanide strength, will be inadequate for the sandy portion, whereas if treatment be adjusted to the requirements of the sand, then unnecessary time, power, and cyanide is expended on the slime.

Sound practice would seem to demand one of two alternatives: (1) an actual grinding of the entire ore to pass No. 200 mesh, and treatment by agitation; or, (2) a modified scheme of re-grinding to reduce the sand to a size shown to be suitable by careful experiment, and then an elimination from the pulp of all material which will not pass a No. 200-mesh screen, followed by leaching, leaving only material finer than No. 200 for the agitators.

As regards the first alternative, there are undoubtedly cases where the extraction increases almost in proportion to the degree of comminution, and on such

ores there is a strong argument in favor of a genuine sliming of the whole, though even here it is not enough to know that a higher extraction will result; the question is, will the additional extraction so obtained more than pay the additional cost? Those who have had to do with reducing ores to a fine state of subdivision will know that the difficulties and expenses rise as the ore gets finer, and as more of the finished material is eliminated, until it is almost impossible to carry the matter to completion. The first thing to separate is of course the natural slime and fine silica in the ore; next, the most friable portions will yield to disintegration, and so on, until there seems to be left a residuum of the toughest and most refractory material. This latter will circulate round and round the milling system, only a small part being eliminated each time as a finished product. Thus the question arises, does it pay to try to reduce this 20 to 30% to a state of slime, even if experiment shows a higher extraction to be obtainable by so doing? This is a serious question, and can of course only be determined for each individual set of circum-

Arrangement of Vat and Distributors.

stances. If, however, it should be finally decided that that it does not pay, why carry on the subsequent cyanidation as if all-sliming were really the method in use, instead of frankly admitting that a varying proportion of the pulp is not slime, and treating that portion in the way most suitable to it?

Coming now to my second alternative, namely, a modified scheme of re-grinding, followed by the removal of everything that is not slime, and a treatment of the two products by separate methods—the two companies already referred to as aiming at an all-slime pulp, though with indifferent success, finally decided to abandon the attempt, and while still continuing to produce a fine material in their tube-mills, separated what would not pass No. 200 mesh, and erected a leaching plant for treating it. The result was that, with the same crushing units, and with no increase of power or expense, they were able to increase the tonnage 50% or more without decrease in the total extraction. In another case the elimination of the percolable portion of the pulp, besides affording the possibility of increasing the capacity of the mill and cyanide plant, yielded a higher total extraction than when treating the whole as an agitation product, and incidentally showed a saving of about 40 cents per ton in costs for power, filtration, and cyanide.

In what I have said I am not comparing the old

method of leaching the sand and agitating the slime with the later one of sliming, or trying to slime, everything. Most silver ores probably give an increased extraction with increasing fineness up to No. 100 mesh, and a few up to No. 200. A later method than either of these is to use a modified re-grinding, aiming in the one case to get as much as possible through the No. 100 screen, and as little as possible finer than this, and in the other to get as much through No. 200 as can be cheaply and conveniently done, but in each case to remove from the pulp every-

never be removed by gravity percolation; (4) it is usually advisable to use the vacuum also during the leaching treatment for purposes of aeration, and for finally drying the charge before dumping, for the same reason as given under (3).

I will here describe an appliance I have used successfully for collecting clean charges of extremely fine sand in the cyanidation of silver ores, and especially where milling is done in solution. It is a circular vat which might presumably be of any desired diameter, though I have never used one larger than

25 ft.; where the sand is especially fine it is probably better to use a smaller size, say 10 or 12 ft. diam., as this seems to afford better control of the quality of the charge collected; and to use two, or even three, simultaneously, as may be necessary. This vat has a circular central discharge overflow, of about 2 ft. diam. for a 25-ft. vat, and 1 ft. for a 10 or 12-ft. vat. The pulp is fed into an appliance resembling the ordinary Butters & Mein distributor, except that instead of the pipes being all of different lengths, they are all equal, and extend to within two or three inches of the periphery of the vat; at their extremities they are bent to about a 45° angle, so that they will discharge the pulp against the side of the vat and at the same time afford sufficient power to rotate the distributor. The pulp runs down the side of the vat without any splash, and the sand builds itself up on the bottom in the form of an inverted cone, while the solution and slime flow over the inclined surface and away through the central opening. As the level of the sand rises, the overflow is built up with cast-iron rings 1 or 1½ in. deep, until the vat is full. The distributor is of course suspended from above, and works on a ball-bearing. The rings

Detailed Plan and Section.

thing that will not pass No. 200, and then treat the two products separately by the method best suited to each.

The reason why the leaching treatment has been apparently unsuccessful in some cases where fine-grinding is practised is probably because a good separation of sand from slime has not been obtained. In order successfully to leach a fine sand composed of material ranging from No. 100 to 200 mesh, the following conditions should be obtained: (1) a clean separation, with a minimum of impalpable slime present in the sand; (2) a thorough disintegration of the sand while being transferred from the collecting to the treatment vat; (3) as an almost necessary precedent to (2), a drying out of the collected charge by vacuum before transferring, because the fine sand retains an excessive quantity of moisture, which can

be lowered into place from the platform which sustains the distributor. They are fitted with small iron pegs, one on each side of every ring, and a semi-circular piece of iron, with a hook on each point, and a long handle, is slipped under the pegs; the ring is lowered into place, and the appliance withdrawn. The edges of the ring are offset so as to fit into one another, and thus obviate possible leakage of sand. There are two vertical bars of iron bolted to the casting of the discharge-hole, which act as guides in the placing of the rings. The whole arrangement will be easily seen by a reference to the drawing.

It will be observed that the principle of this collector is entirely different from that of the Butters distributor vat; in the latter the lengths of the pipes are so designed as to distribute sand over the whole area of the bottom, as far as possible, while the splash

is largely depended upon to keep the slime in suspension till it reaches the overflow gates at the periphery of the vat; in the pulp here described the sand settles first at the periphery and the slime rolls over the surface of it till it reaches the outlet. There is never more than a film of solution and slime covering the sand, except for a short distance around the overflow every time a new ring is lowered. To avoid a layer of slime depositing on the filter mat before the sand has formed its own angle of inclination toward the centre, the filter-bottom is made slightly conical.

Sand collected in this way does not pack as it does with the ordinary method of distributing; it occupies more space for a given weight; and when well drained falls apart under the shovel, forming a minimum of obnoxious lumps which are so detrimental to good leaching. When the sand to be collected is exceptionally free there is a tendency to agglomerate even with this system, and it is advisable to transfer to the treatment-vats by means of a belt and tailing-stacker to get the charge thoroughly disintegrated and

Device for Placing Rings.

mixed. Incidentally, this appliance forms an excellent slime concentrator, holding back in the sand all but the finest concentrate in the slime, and giving it the advantage of the extra time and cyanide strength, which it would not get in the agitator vats.

The method of deposition of the sand in this collector is similar in principle to that of the South African 'nigger with a hose' system, with the added advantages of making a cleaner separation, being almost automatic, and having greatly increased precision and regularity. The following are some screen-analyses of material collected in these vats:

| Mesh. | | No. 1, % | No. 2, % | No. 3, % |
|------------------|-----|-------------|-------------|-------------|
| Over | 60 | 21.6 | 5.1 | ... |
| Under | 60 | 22.8 | 15.3 | 2.9 |
| " | 80 | 17.2 | 16.0 | 11.6 |
| " | 100 | 19.9 | 41.2 | 36.8 |
| " | 200 | 14.8 | 17.7 | 43.9 |
| Impalpable slime | | 3.7 | 4.7 | 4.8 |

In No. 1 the sand was collected in a 25 ft. diam. vat; milling was in cyanide solution; and protective alkalinity was 0.1% in terms of caustic soda. A cone classifier was used to remove part of the slime prior to delivery in the collector. In No. 2 the sand was collected in a 10 ft. diam. vat; milling was in cyanide solution; and protective alkalinity was 0.125%. Here also there was a partial removal of the slime by cones prior to delivery in the collector. In No. 3 the sand

was collected in an experimental vat 3 ft. diam.; milling was in cyanide solution; and protective alkalinity was 0.15%. The pulp was taken direct from the mill-laundry without previous classification, and no return 'spitz' was used to trap the sand which might have escaped from the collector. The charge of slime separated from this sand only carried 3% of sand coarser than No. 200 mesh.

These three examples are from different mines treating diverse kinds of ore. No. 3 will illustrate the possibilities of this method of separation. The resulting charge of sand, when transferred, percolated by gravity at the rate of $1\frac{1}{2}$ in. per hour through 3 ft. in depth, during a period of 14 days treatment. I believe that as a separator and collector of exceptionally fine sand in a highly alkaline pulp the device described is unsurpassed by any method at present in use. I have not patented it, because, while the application to collection of sand for cyanide leaching is, as far as I know, original with me, yet the principle is that of the old Cornish concave buddle fed by a modified form of Butters & Mein distributor. I have described it at some length, in the hope that it may meet the needs of other workers who

Ring-Shifter.

have been confronted by the necessity of fine-grinding and who yet recognize the difficulty and expense of all-sliming.

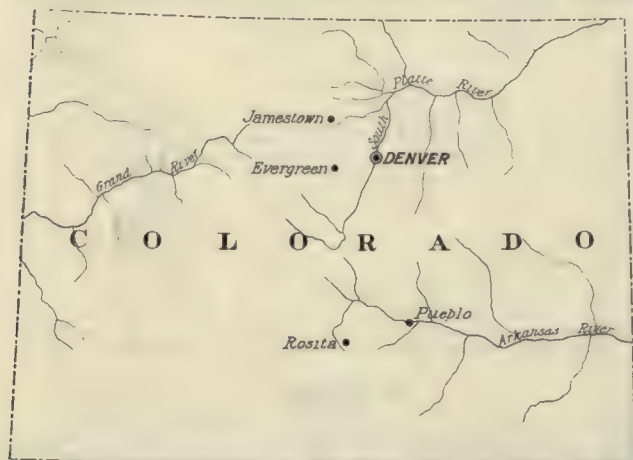

The Taylor Peak and Whitepine iron-ore deposits of Colorado are described by E. C. Harder in an advance chapter of the U. S. Geological Survey's Bulletin 380. The Taylor Peak district is in the eastern part of the Elk mountains, on the boundary between Pitkin and Gunnison counties. The nearest town, Ashcroft, in southern Pitkin county, is about three miles south of the principal deposits. The ore deposits are on the north, east, and south sides of Taylor peak, about 10 miles west of the junction of the Elk and Sawatch ranges. They are all above timber-line, ranging in elevation between 12,000 and 13,000 ft. The largest single deposit is on the north slope of Taylor peak, at the head of Cooper creek. It has an average length of about 750 ft. and an average width of about 450 ft., and has been estimated to contain between 3,000,000 and 4,000,000 tons of ore. The Whitepine district lies on the west slope of the Sawatch range about 10 miles north of Marshall pass, in the southeastern part of Gunnison county. It is readily reached from Sargents, on the narrow-gauge line of the Denver & Rio Grande railroad, at a distance of 12 miles. The principal ore deposits lie on the east slope of the valley of Little Tomichi creek.

FLUORSPAR IN COLORADO.

Written for the MINING AND SCIENTIFIC PRESS
By ERNEST F. BURCHARD.

*The fluorspar deposits of Kentucky and Illinois have received considerable attention from mining men and geologists. Little, however, has been published regarding the Colorado deposits. The following notes based on a hasty reconnaissance by the writer in September, 1908, may, therefore, be of some interest.

In Colorado and other Western States fluorspar occurs commonly in small quantities in connection with metalliferous veins. In eastern Colorado, in a narrow belt extending more than 150 miles from north to south, just within the front range of the Rocky Mountains, from Boulder county on the north to Custer county on the south, fluorspar occurs in considerable quantities. In several places it forms the major part of the filling of certain fissure veins in which the metalliferous minerals are practically of negligible quantity. The fluorspar veins,

Map Showing Fluorspar Localities.

where studied, cut granites and gneisses of pre-Cambrian age that have been intruded by later dikes, many of which are of quartz porphyry.

The fluorspar industry in Colorado is yet in its infancy. In milling the precious metal ores some fluorspar is obtained in the tailing. But little of such spar can be saved. Where the veins are wholly of fluorspar and thick enough to yield an important tonnage, attempts have been made to mine the spar itself, although with but little mine equipment. All the deposits thus far worked are situated 12 to 16 miles from a railroad. Much of the spar, heretofore, produced has failed to fulfill the requirements of the market on account of the presence of wall-rock and vein materials which are difficult to separate without special machinery. Gravel spar is the only grade that can be prepared by hand-cobbing and sorting. The lowest grade of spar acceptable must contain at least 80% CaF_2 , with silica less than 15%. There is at present a local demand for more spar than can be produced in the State at the present rate. Colorado spar is fairly free from ob-

jectionable sulphides, and the basic open-hearth steel plant of the Colorado Fuel & Iron Co., at Pueblo, consume practically all the output of the State, and about twice as much more which is brought from Illinois and Kentucky. The price paid for Colorado spar is \$6 per short ton for spar that carries 85% CaF_2 , f. o. b. cars at Boulder, Morrison, and Westcliffe. A premium of 20c. per ton for each per cent of CaF_2 above 85 brings the price of 90% spar up to \$7 per ton, and a deduction of 20c. per ton for each per cent of CaF_2 below 85 reduces the price of 80% spar to \$5 per ton.

Simple and economical methods of cleaning the spar, and better transportation facilities, are the things most needed by the fluorspar industry in Colorado. There seems but little prospect of bringing railroads any nearer to the present working properties for some time, but discoveries of new deposits of fluorspar nearer to railroads are likely to follow. The general improvement of wagon-roads would be possible and beneficial.

The principal materials that must be separated from the Colorado fluorspar in order to raise its grade are quartz, clay, granitic rock from walls and breccias, and silicious gouge—in general silicious and aluminous materials whose specific gravities are a little lower than that of fluorspar. It would seem feasible to raise the grade of most of the Colorado material at least to the minimum limit, and of the best grade to at least 90% CaF_2 , by the application of some of the simpler cleaning processes now employed in the Kentucky-Illinois district. The problem in Colorado is to save only the fluorspar (except in rare instances where ores of lead, copper, zinc, or the precious metals may be present), and to put quartz, feldspar, sand, rock, clay, etc., into the tailing. The differences in specific gravity (fluorspar 3.13, quartz 2.65, feldspar 2.7) are relatively slight; therefore, the most perfect separation would involve a practically perfect sizing system of screens and jigs. Such elaborate equipment is out of the question at present in Colorado for several reasons, chief among which are (a) the quantity of spar in sight does not warrant large operations; (b) water is not abundant at most of the fluorspar prospects, and washing operations probably could be carried on only during part of the year; (c) the cost of haulage is so great as to cut down profits to such a low margin that returns on large investments could hardly be realized. A much cleaner product, however, might be procured by coarsely crushing the spar, running it down a gravity washer or through a log washer to remove the clay and sand, and subsequently picking out the large fragments of quartz and rock. The picking could be done on a table or belt. One such outfit would suffice to handle the whole output of each district in the State.

There are three localities in Colorado where fluorspar is produced for the market, namely, at Jamestown, Boulder county; at Evergreen, Jefferson county; and near Rosita, Custer county.

At Jamestown the country rock is generally granitic, of pre-Cambrian age. The granite is intruded by several dikes of quartz porphyry, which carries

*Published by permission from the Director, U. S. Geological Survey.

fluorite in quantities ranging from a trace to 30%, and is cut by many true veins, in which the vein material is principally crystalline fluorspar, with crystalline quartz and pockets of decomposed silica and feldspathic clay. There are veins carrying quantities of sulphides and tellurides also in the vicinity, but these are not worked for fluorspar. The fluorspar veins here are notable for their lack of metalliferous minerals. The mineralized zone that carries fluorspar in abundance extends northwest-southeast for about 2 miles, with Jamestown near the middle. The width of the zone is about one-half mile. The valley of Jim creek cuts through this area and affords out-crops of the fluorspar veins and other mineralized dikes and veins. Within a radius of one mile from the centre of the village there have been located ten or more groups of claims on which fluorspar veins appear to be abundant. The fluorspar veins occupy fissures, and the walls and vein material seem to have suffered some modification by movements which have resulted in the brecciation of the material to some extent. The wall and vein materials are thus more or less intermixed, and the veins appear to be faulted in places so as to be offset. The fluorspar veins range in width from a few inches to 15 ft. Veins less than 1 ft. wide can hardly be worked profitably, and there are few that exceed 6 ft. Thicknesses greater than 6 ft. are generally due to local swellings or to intersections of two or more veins. The usual width of the veins is from 2½ to 5 ft. The fluorspar veins according to strike fall into two groups, those striking northeast and those striking northwest, the former group predominating. The veins are nearly vertical, or dip at angles of 75° or more. The veins show faint banding or ribbon structure, but this in many cases has been obscured by brecciation.

The fluorspar in this locality is generally dark-colored, ranging from greenish brown to dark purple, although there is some light-colored, fairly clear, glassy spar obtainable. A singular characteristic of the dark spar is that on exposure to sunlight and air the darker color bleaches to pale purple, light blue, or white in a few months. This is true of the spar on the surface of outcropping veins, as well as of mined material thrown out on stock piles. The spar that has been opened is mostly near the surface and it is generally much fractured, rather porous, and somewhat brecciated. The cracks, pores, and cavities are filled with decomposed quartz and feldspathic material, and this, together with the vein quartz and wall material which is necessarily included in mining, greatly reduces the grade of the spar. The material as mined, carries 70 to 85% CaF_2 .

Among the more important fluorspar properties at Jamestown may be mentioned the Blue Jay group of claims owned by Joseph Bergheim and William Brown. At the Blue Jay there are two adits, the upper about 100 ft. long and the lower about 90, each in ore for about 75 ft. The vein is 4 to 5 ft. thick, strikes N. 70° W., and dips at an angle of about 70° toward the northeast. The vein lies between walls of decomposed, grayish, granitic rock,

and within the vein are pockets and crystals of feldspar and quartz. The spar is dark purple without marked vein structure. The material is much fractured and shows seams of iron oxide. When struck with a hammer in the dark, the ore shows phosphorescence. There are several other veins in the vicinity running parallel to those which are cut by the adits. One of these veins is reached by a shaft. At the top this vein shows 2½ to 3 ft. of spar, and it is reported to widen to 10 ft. or more at the bottom of the shaft, 112 ft. deep. The vein pitches steeply to the west and the shaft follows the vein. The water level lies at about 40 ft. below the top of the shaft.

The Yellow Girl property contains a vein now nearly worked out, but which once yielded 1700 tons of spar to 5 men working 27 shifts. There was an unusual thickness of ore, 6 to 12 ft., in the veins in this property. This extreme width was due to a pocket; the vein where widest is sheeted, giving the spar the appearance of a bedded formation, especially where some spar is left to form the cap over the entrance to a short adit. The wall-rock at this place is granite, and there is much quartz associated with the fluorspar in the vein. There are also pockets of amorphous, silicious material resembling tripoli. At the end of the adit, the ore is apparently cut off by faulting against a wall of decomposed gray granite containing much pyrite.

The Emmett mine has opened a vein which shows a thickness of 6 to 15 ft. The maximum thickness occurs at points where the vein apparently forks. The main vein strikes N. 70° W., and dips steeply toward the northeast. The spar is mostly of a dark purple color, but there is some white to pale green, translucent, practically pure spar. The workings here consist of surface cuts some 50 to 60 ft. long, and an adit 85 ft. long stoped overhead to heights of 8 to 20 ft. The rock is moved by hand trams and dumped into a chute, which conveys the material to a bin at the roadside 160 ft. below. The owner of this property is William Brown, who owns also the Invincible mine (a producer of sulphide ores), which lies almost in the strike of the fluorspar lead. Other properties of promise are the Early Bird prospect and the Tip Top claim owned by C. E. Beach; workings owned by John Evans; and the Lookout lode, which formerly was worked as a gold prospect.

Although mining of fluorspar has been carried on near Jamestown for 6 years, the development work thus far accomplished consists mainly of surface cuts and adits not more than 100 ft. long. Much of this work has simply been done as assessment work. Overhead stoping from the adits has opened the spar in places to vertical distances of 30 ft. As already mentioned, one shaft has been sunk on a fluorspar vein. It is reported that this shaft is 112 ft. deep, that from it levels were driven north and south on the vein at depths of 50 and 100 ft., and that the spar has been mined out to the second level by overhead stoping. In September, 1907, this shaft was partly filled with water. All the fluorspar workings here, except this shaft, are well above the level of ground-water and are easily drained.

The statistics of production of spar from Colorado were not obtained at the beginning of the industry, so it is probable that considerably more spar has really been mined from here than has been recorded by the United States Geological Survey. The Colorado returns date back to 1905 and total less than 6000 tons. The total quantity produced in the Jamestown district, according to rough estimates made by men familiar with the locality, amounts to about 8700 short tons. On the majority of claims only assessment work is done from year to year, the crude spar which is mined being hand-cobbed or perhaps hand-screened and allowed to accumulate until the weather and roads are favorable for hauling. The product is of the grade known as 'gravel' in Illinois and Kentucky. The spar must be hauled to Boulder, a distance of $13\frac{1}{2}$ miles by road, which is mostly down-grade. The cost of hauling is about \$3 per ton.

Near Evergreen, Jefferson county, along Bear creek, is an area of pre-Cambrian granite-gneiss, in which fluorspar occurs in true veins, associated with minor quantities of lead, zinc, and copper minerals. Besides the veins in which fluorspar is the major constituent there are quartz veins carrying minor quantities of fluorspar as well as metallic sulphides.

On the northwest side of Cub creek, a branch of Bear creek, at a point about $\frac{3}{4}$ mile southwest of Evergreen postoffice, a prospect has been opened by R. P. Blakeslee on a fluorspar vein, ranging from $1\frac{1}{2}$ to $4\frac{1}{2}$ ft. thick, and averaging $2\frac{1}{2}$ ft. of spar. The vein strikes N. 30° W., and dips 70° to the southwest. The vein fills a fissure which cuts across the sheeting of the granite. It is reported to be traceable for about one mile to the southeast and for a greater distance to the northwest. The Augusta mine, formerly worked for ores of copper, is nearly in the same strike about $\frac{1}{3}$ mile to the southeast. The walls of the vein show movement. Strained and mashed biotite-granite occurs between the vein material and the walls of the fissure. Fragments of it penetrate the vein material at the edges. Within the vein there are in places bands of white quartz 1 to 3 in. thick and bands of silicious biotitic rock 3 to 6 in. thick. Along the foot-wall the vein carries small quantities of lead and copper ores. Blende is reported from below ground-water level. The fluorspar is banded parallel to the walls and its color ranges from amethyst to deep purple, from pale to deep green, and in a few places it is greenish yellow. It is mined from hillside open-cuts and drifts on the out-crop, and the vein has been reached also by a cross-cut about 250 ft. long below which a winze about 25 ft. deep was sunk, and from this a lower level was driven a few feet. The spar is mined by hand, hoisted to the surface by windlass, hand-cobbed, the metalliferous minerals saved, and the products hauled $12\frac{1}{2}$ miles, mostly down grade, to the Colorado & Southern railway at Morrison. The haulage costs \$2 per ton.

In September, 1908, mining was in progress, but shipments were suspended owing to washouts on Bear Creek road. Some fluorspar was mined here in the seventies and carted 28 miles to Central City, where it was used in smelting gold and silver. The

present workings were opened in December, 1907. The total product for the year was about 200 short tons. The material is now used by the Colorado Fuel & Iron Co., at Pueblo.

About 7 miles southeast of Rosita, Custer county, near one of the branches of Antelope creek, a vein carrying fluorspar has been discovered, from which some spar has been produced for the market. The rocks in the vicinity are pre-Cambrian granite and gneiss and later eruptives. The fluorspar occurs as a shoot in a fissure vein cutting the crystalline rocks. The vein strikes N. 20 to 30° E., and dips 70 to 75° toward the southeast. The shoot is a well defined tabular sheet of ore, pitching northwest. It pinches and swells locally, and terminates on its lower right hand margin in silicious vein-rock. It is also slightly faulted, as shown in one of the upper workings. The thickness of the vein varies from 16 in. to 4 ft., and the irregularity is more pronounced in the hanging wall than in the foot-wall. The thickness of the spar ranges generally from 2 to 3 ft., and the average thickness of the workable material averages about $2\frac{1}{2}$ ft. Between the wall-rock and the workable spar there is in places a band of brecciated silicious rock 4 to 6 in. thick, cemented by fluorspar, and generally there is also a clay gouge $\frac{1}{2}$ to 6 in. thick. The spar is light green to brown in color, and rarely bluish. It is rather finely fractured and is also jointed. Filling the fracture and joint planes are films and seams of brown, smooth clay, but the material is relatively free from quartz and silicious matter except near the walls of the vein. About one-quarter mile northeast of the out-crop of the fluorspar vein and striking nearly at right angles to the latter, copper-bearing veins have been opened. Fluorspar is present as a minor gangue material.

The property from which fluorspar is obtained here has been worked by J. C. Steiner and D. D. Moninger, and recently the Jocomo Mining Co. has been organized to exploit the property. The workings consist of an adit with two drifts, respectively 80 and 100 ft. above the adit, all driven in the direction of the strike of the vein. There is one additional level 13 ft. below the lower drift. The adit was driven 200 ft. from the outcrop in barren vein material, and the ore-shoot was reached about 50 ft. higher on a raise, driven from the adit. The spar is worked by stoping in the levels and is milled down the raise to the adit, out of which it is trammed by hand to a storage bin. Only hand methods of cleaning the ore are employed, and the product is hauled by wagons to the Denver & Rio Grande railroad at Westcliffe, a distance of about 16 miles, the first 6 or 7 of which are over a rather hilly road.

The fluorspar thus far shipped from the Rosita district has generally been kept well above the standard, as shown by the analyses below. The product, nearly 1000 short tons, has been purchased by the Colorado Fuel & Iron Co., at Pueblo, on the same conditions with regard to grades and prices as elsewhere in Colorado. The same problems confront the producers, namely, the production of a spar which shall carry 80% or more CaF_2 without

a large proportion of waste or a large expense in cleaning and transporting it to the railroad.

The more important points brought to notice by this reconnaissance are (a) that the fluorspar deposits are fissure veins that probably extend to considerable depths; (b) that the veins are of moderate thickness as compared with those of the Ohio River, in the Kentucky-Illinois, district, and that the quantity of spar probably does not warrant any but simple and inexpensive equipment for cleaning and concentrating; (c) that the fluorspar is generally free from sulphides and that, although some of the run-of-mine material is acceptable in the crude state, the greater part of it needs some cleaning in order to render it marketable; (d) that there is a steady local demand for more spar than is yet produced in the State; (e) that the geological conditions appear favorable for the occurrence of much more fluorspar than has yet been discovered, and that further prospecting for the mineral is therefore to be encouraged.

Seward Peninsula and the mining conditions there have been described recently in Bulletin 379 of the United States Geological Survey by P. S. Smith, F. F. Henshaw, and A. H. Brooks. The resource of chief value in Seward Peninsula is placer gold, and these reports show that the low-water conditions of 1908 and the approaching exhaustion of some of the ancient rich beach placers considerably curtailed the production. The value of the output of placer gold in Alaska for 1908 is estimated at \$15,455,000, of which Seward Peninsula furnished nearly a third, or about \$5,000,000, as against \$7,000,000 in 1907. The 1908 output of the Peninsula is about the same as that for each year from 1900 to 1905—that is, the same as before the ancient beaches at Nome were discovered. The average production for each placer mine for the year was over \$16,000, a figure which indicates that many of the operations were conducted on a large scale. The average output per placer claim was \$2300; if the men engaged in dead work and prospecting are also included, the average per man was \$1400. These figures are somewhat

higher than those for the whole of Alaska, owing to the fact that many labor-saving devices are in use in Seward Peninsula and that most of the small plants were closed in 1908 for lack of water. Bonanza mining is still dominant in this region, with the result that methods of working low-grade gravels have not been developed as they must soon be if the production is to be maintained. One of the prime necessities in the future progress of the placer-mining industry of Alaska is the guidance of experienced engineers who are capable of solving any problem that may arise in the development of gravels which are not rich enough to allow a wide margin between success and failure.

SAVING GOLD WITH HUNGARIAN RIFFLES.

That gold is readily saved by the Hungarian riffle sluice is shown by the following tests, which at the same time were intended to determine what effect might be produced by varying the amounts of solid matter in suspension in the pulp-stream sluiced. The Hungarian riffle is one with a lip projecting down-stream. The pulp accordingly eddies under

Hungarian Riffle Sluice.

each lip, thus checking the velocity, and giving the gold a chance to settle to the bottom. Each test consisted of 2.52 cu. ft. of gravel and sand into which was thoroughly mixed 814.15 mg. of gold. This was put through a sluice 7 ft. long, 8 in. wide, riffle surface 4 2/3 sq. ft., grade 1 in. to the foot. The water in the first test contained 22.2% solid matter; in the second test clear water was used. The recovery was 80% in the first and 83% in the second test. The ratio of this sluice area to that used on the dredge is as one to three. Since no particular care was taken not to lose the gold the results show a fairly good recovery. The experiment was crude, but suggestive. It is apparently of more consequence to maintain a proper depth of pulp over the riffles, and a proper grade to the sluice, than to preserve uniformity of dilution in the pulp. Those factors bear upon the production of a suitable eddy. It would be interesting to make further tests to ascertain the best shape of Hungarian riffle.

DIAMOND DRILLING AT TONOPAH.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN M. FOX.

In the autumn of 1908 it was decided to put down a vertical drill-hole from the bottom, or 700-ft. level, of the Silver Top mine to gain information regarding the formation through which the Silver Top No. 1 shaft would have to pass if sunk to greater depths. A station and raise were cut close to the shaft and the drill installed. The height of the raise was sufficient to enable the runner to pull in 20-ft. lengths. A suitable sump was cut near by for return-water from the hole, thus permitting the use of the same water repeatedly, with the exception of what was lost in the hole.

The drill was a Sullivan Class 'C', provided with a hydraulic head and chuck for size 'A' rods, capable of drilling to 1500 ft. The engine, drum, and

Sullivan Drill Underground.

head were mounted in the usual manner, on a standard frame, which was held in place by two heavy sprags wedged to the wall of the station. Compressed air at 90 to 100 lb. pressure was used for motive power, it being tapped from a main-line through a 1-in. connection to the engine. As the level is dry, water for the drill was drawn from the water-pipe line in the shaft. Since a 700-ft. head would have provided a higher pressure for the drill than was desirable, a break in the line was made at the 400-ft. level. A large sheet-iron tank was installed at that point, and the supply-pipe from above was provided with a valve that was opened and closed automatically by a float. From the tank to the drill approximately 300 ft. gave about 123 lb. water-pressure, sufficient for the ordinary operation of the feed. In actual running, the hydraulic head was supplied entirely from this source, proving perfectly satisfactory, as it gave clean water at

a constant pressure with no entrained air. The latter is objectionable, giving rise to 'jumping' in the rods, with attendant extra wear on the diamonds. As stated above, the water at the bit is used many times. As it flows from the collar of the hole, it is collected in the sump, and from there pumped by a small duplex back through the rods. The supply, of course, has to be replenished from time to time, as some water is lost.

At the start, the hole was reamed to a depth of 3 ft., and a 2-in. inside diameter pipe wedged in it. This projected high enough above the collar to allow the sludge-board to be placed, when actual drilling began. Size 'A' rods (standard), having an outside diameter of $1\frac{5}{8}$ in., were used. To these were strung a 10-ft., size 'A,' plain core-barrel, straight core-shell for 'Cosette' core-lifter, and size 'A' bit. The latter has an outside diameter of $1\frac{25}{32}$ in. With the carbons having a total offset of $\frac{1}{32}$ in., the diameter of the hole, assuming a perfect bore, would be $1\frac{13}{16}$ inch.

Some trouble was experienced with the 'Cosette' core-lifter on account of the breaking of fingers, due probably to the fact that fragments of rock would wedge between the fingers and the frame on which they were mounted. As the core rose through the lifter, some irregularity on it would tend to force the fingers back against the springs which hold them out toward the centre of the core. Being unable to retreat because of the rock behind them, they would snap off. When a core-lifter is working properly, it would have little or none of the rotation of the rods, but should slip easily within the core-shell. Its relation to the core, when the latter is not broken off to the bottom, should be that of a stuffing-box to a piston-rod. Of course, such a perfect adjustment is unattainable, but it should be as closely approached as possible, otherwise the gripping edges, no matter what type of core-lifter is used, will be rapidly worn away and will lose their ability to hold the core when the time comes to pull.

The diamonds or 'carbon' in use averaged, when new, about $3\frac{1}{2}$ carats each. They were of the best quality, and at the existing market price cost \$75 per carat. Six stones were set in each bit, three inside and three out, with a $\frac{1}{64}$ -in. offset. The life of a new bit varied greatly in this hole; some drilled 35 to 40 ft. before becoming played out, others were retired after drilling only 2 or 3 ft. Many causes contributed to this difference in life. Vibration in the rods causes great wear and tear on both stones and metal. Short-fissured ground makes bad drilling, and variable pressure at the feed, which is hard on the bit.

Too great emphasis cannot be laid upon the advisability of buying the best carbon. Unless one is an expert by reason of long experience in judging stones, the setter should do the picking. There are few arbitrary rules by which a stone can be judged as to its worth. Its shape is almost as important as its quality, and the setter, if he be competent, is certainly the best judge of that characteristic. There are unscrupulous dealers in carbon, as there are in every line, and they have their ways of de-

vided a means of cutting away slight obstructions that might get in the way while lowering the casing for the last time. They were worthless for any other purpose, and hence were left in the hole. From here on, work progressed without serious trouble, occasional soft streaks being cemented; at 411 ft. the water was lost completely; in fact, it ran away so rapidly that the sump was siphoned dry. Sawdust and bran proved ineffectual in plugging the outlet, and until cement was used, the water continued to escape.

Experience gained in cementing sections of this hole may prove of use to others. In the first place, certain brands of cement are more adaptable to this work than others. Those reaching their initial and final set the most rapidly, are obviously the best on account of time saved. The character of the ground being drilled may cause more or less alkalinity in the water. This seems to retard the setting of some cements more than others. In making the mixture it was found that the thicker it was, the better; the limit to which the thickness may be carried, depends upon whether the cement is to be poured or not. For comparatively shallow holes, pouring answers very well; for deeper holes, placing thick cement in paper tubes about 12 to 14 in. long, and dropping into the hole, has been tried with success. Three important things to be observed to secure the best results are these: first, get the hole dry, if possible, by blowing; second, tamp the cement frequently while putting it down, which can be done by plugging the end of the rods and giving them a slight drop on the brake (of course, it takes much more time than simply pouring in the cement and allowing it to set, but the results are more certain, and in the long run, time will almost always be saved); third, if a brand of cement prove unsatisfactory, try others. One can probably be found to do the work.

Vibration of the rods, which is mentioned above, can be greatly reduced, if not eliminated, by coating them with crude petroleum when lowering. This provides a lubricant that clings in spite of the scour of water and sludge.

Record of hole: there are probably as many systems of keeping the log of a diamond-drill hole as there are districts in which such work is being done. The following figures will show one such system, which is really in triplicate. The first record is composed of type specimens selected from each day's run; if the core shows no variation for that day, one piece is taken to represent the rock drilled; any change or changes shown in the hole are recorded by corresponding pieces taken from the core; each piece has painted upon it the depth

it represents. The diagram of the hole is drawn to a vertical scale of 5 ft. to the inch, with the width greatly exaggerated. A plate is made for each 100 ft. drilled; on these plates are recorded depth, formation, assay values, and eventually the petrographic description of the rock, wherever it has been deemed advisable to have slides made, will be added. The ledger record explains itself.

Assays: sludge-samples were taken from every run and assayed. Core samples were taken from time to time as a check, or wherever it was thought necessary by reason of the appearance of the core. It was realized that sludge-samples are only indicative of the presence or absence of valuable material when drilling under such conditions as the above. No reliability can be placed upon them quantitatively for many reasons: for example, a high-grade streak of narrow width would salt a 10-ft. run. If one succeeded in coring the streak and its adjacent walls, reliable information would have been gained in regard to where the valuable material came from, but without such proof, no certainty could be felt as to whether the ore were 10 ft. wide, and low in value, or one or two inches wide, and high in grade.

Costs: to one unfamiliar with conditions in Tonopah, the cost of drilling will seem strangely high. Labor and power, the two main items, probably reach a maximum there, yet in spite of this, in one month when 190 ft. were drilled, the cost per foot was only \$3.50. In calculating costs for this hole, nothing was omitted that should be charged against it, and in fact, in one or two instances, it has borne unjust charges through an imperfect understanding of the conditions. The following list of charges gives an idea of how the cost was arrived at: (1) power (based on the drill's proportion of total air consumption); (2) labor; (3) diamond loss; (4) water (for the first four months only; after that, the 200-ft. level made enough water to supply both diamond and machine drills); (5) assaying; (6) supplies (includes pipe, bits, tools, cement, oil, etc.); (7) proportion of compressor repairs; (8) machine-shop work done directly on drill and equipment.

The table on page 263 will give a condensed statement in regard to progress, costs, and the like. It was kept by me for my immediate use, and has been of service in supplying quick information regarding such headings as it contains.

The Western Australian Mining Law is based on two fundamental principles: (1) that land shall be utilized for that purpose for which it is most valuable, and (2) that no man may hold mineral rights without development. Enforcement of the latter leads to the provision that none of the minerals to which the Government holds title shall be sold, but the Government may authorize the working of the mineral deposits by those conforming to the requirements of continuous development.

Water is commonly taken as weighing 62.5 lb. per cubic foot. The actual weight is 62.425 lb., at a barometric pressure of 30 in. and a temperature of 39.1° Centigrade.

Drill Record Plotted.

WEIR MEASUREMENTS.

The term 'weir' is not always understood by those who use it. The term can properly be used only for structures designed to allow the water to flow over the crest with a considerable fall on the down-stream side. There are a large number of forms of weirs, taking their names from the shape

at an angle equal to 1 in. horizontally for every 4 vertically. Thus, for each additional inch in depth the weir notch widens on each side one-fourth of an inch, or a total addition of width of one-half inch. A weir having a length of crest of 1 ft., and designed to be 8 in. deep, will have a top width of notch of 16 in. The working drawings herewith show how such a weir can be constructed.

Working Drawings for Construction of Weir Box.

When the weir box is placed, care should be taken to have the bottom of the notch, or crest, level. An ordinary carpenter's spirit level may be used for this purpose. When the crest is horizontal, one end of the spirit level is placed on the centre of the crest, and when level the other end will mark the point for the zero of the weir gauge. In rough work a nail may be driven part way into the side of the box, the top of the nail being level with the crest of the weir. A thin plate of brass is to be preferred to a nail. In other cases gauges are inserted on the sides of the flumes and properly marked in tenths of feet or inches. At other times a post from 1 to 2 in. square is placed in the centre of the box and several feet above the weir board. The top of this post is on a level with the crest.

The method of measuring with this weir can best be shown by examples. Let us suppose that the engineer has made and placed a box similar to the one shown in the drawing. After turning in the water and allowing it some time to attain a uniform flow he proceeds to the weir box, and with an ordinary rule measures the depth of water flowing through the weir notch. Bear in mind that this measurement is not made at the weir board, but at the regu-

Weir Box in Operation Showing Rod for Measuring Depth of Stream.

lar gauge, whether it be a nail, brass plate, or post as already described. We will assume that the depth as found by the rule is 3 1/2 in. Now by referring to the table below, he follows down the first column until 3 1/2 is reached. The weir used is one foot, and under the column marked '1-foot weir' and opposite the figure 3 1/2 already found he finds the cubic feet per minute or the gallons per minute flowing over a 1-ft. weir when the depth of water is 3 1/2 in. The equivalent flow in gallons per minute

of the weir notch, or form of crest. The triangular weir has a V-shaped notch. The rectangular weir has a horizontal crest with vertical sides. Both of these forms of weir are good, when used by engineers who understand the principles and factors which enter into their calculations. In order to avoid the variables, Cipoletti invented the form of weir which has taken his name and which is in general use.

The Cipoletti weir has a thin horizontal crest, the sides of the weir notch sloping back from the vertical

for any given length of weir and depth of water over the crest was obtained from the following table:

Weir measurements have generally superseded the older methods of measuring 'miner's inches', though the latter term is still widely used. The quantity of water forming a miner's inch is defined in different States. In California and Montana it is 1.50 cu. ft. ately, has lowered the total for that centre. Queensland about holds its own, but Western Australia and New South Wales each report lower returns. The figures for the Commonwealth for the quarter are 51,267 oz. below those for the same term last year, and for New Zealand 14,548 oz. The returns for the Commonwealth and for Australasia for the past

U. S. GEOLOGICAL SURVEY FIELD WORK.

Field work of the United States Geological Survey in the Western States this season includes an examination of the phosphate lands of Idaho, Wyoming, and Utah by Hoyt S. Gale and Eliot Blackwelder, assisted by a chemist detailed from the Bureau of Soils. F. L. Ransome, assisted by E. S. Bastin, will study the Breckenridge, Colorado, mining district. Waldemar Lindgren and B. S. Butler will investigate the ore deposits at Frisco, Utah, where W. M. Beaman has been making a new, large-scale, topographic map. Mr. Lindgren, assisted by Howard Bancroft, will also report on the Republic mining district of Washington. F. C. Calkins will conduct surveys in northeastern Oregon, F. L. Hess at Randsburg, and Robert Anderson at Bakersfield, California. Whitman Cross will continue his work in the San Juan district of Colorado, working near Durango, and A. C. Spencer will study the mines and ore deposits at Ely, Nevada.

The coal land classification surveys will continue under charge of M. R. Campbell, who is making Denver his headquarters and visiting various field parties from time to time. L. J. Pepperberg is in charge of a party in the Mills River coal-field of Montana; C. T. Lupton and party will cover the Bull Mountain and Lower Powder River fields in Montana and Wyoming; W. R. Calvert will map the territory north of Livingston, Montana; C. H. Wegemann will survey the Powder River field, and E. G. Woodruff the Wind River Basin field; J. A. Davis will map the Yampa, A. L. Beekly the Glenwood Springs, W. T. Lee the Crested Butte, and J. H. Gardner the Durango field. G. B. Richardson will work in the southwestern New Mexico field. E. E. Smith, in co-operation with the newly organized State Survey, will work in Washington. J. S. Diller will study the Coos Bay coal-field of Oregon.

Topographic surveys in the National Forests are being especially pushed in view of their value not only in administration but in development of water and mineral resources. The assignments are as follows: Shoshone Forest, E. I. Ireland; Cache, Albert Pike; Caribou and Cache, A. E. Murlin; Holy Cross, E. R. Bartlett; Alamo, W. H. Manning; Gila, A. B. Searle; Lola, W. J. Forster; Couer d'Alene, W. O. Tufts; Bull Run, R. M. La Follette; Trinity, J. P. Harrison; Sierra, C. H. Birdseye; Washington, J. E. Blackburn. Crater Lake Park is being surveyed by Pearson Chapman; R. B. Marshall, Chief Geographer, is revising maps of Yosemite, Sequoia, and General Grant National Parks.

Co-operative surveys of the Sacramento valley are being made by W. H. Griffin, F. H. Moncure, and A. F. Fowler, and of the Willamette valley by Robert Muldrow. G. R. Davis, C. G. Anderson, and C. M. Weston will execute surveys in the vicinity of Hawthorne, Bridgeport, Mt. Goddard, McKittrick, Coalinga, Cantaur, and Salinas, California. In Washington, surveys of the Mt. Vernon, Morrison, and Quincy quadrangles will be made during the summer, and in the winter the Winkleman, Arizona, and Ivanpah, California-Nevada, quadrangles. At Medows, Idaho, A. O. Burkland, at Cutbank, Montana, R. W. Berry,

at Montrose, Colorado, Gilbert Young, and at Havre, Montana, W. L. Miller, are at work. C. L. Nelson is surveying and marking the Washington-Idaho boundary line. River profile surveys and special examinations are also being made at numerous points following with withdrawals of public land in connection with proposed legislation regarding water-powers.

PHILIPPINE PLACER MINING.

The operations of the Paracale Gold Dredging Co., Ltd., for the six months ended December 26, on the Paracale river, Camarines, Philippine Islands, show an average production of \$1 gold from every cubic yard of dirt dredged during that period, according to the *Far Eastern Review*. This is verified by the dredgemaster's daily report and corroborated by the statement of the International Banking Corporation. The former shows an actual dredging time of 2735 hours, with 50,244 cu. yd. of dirt handled, and the bank statement shows that 2814 oz. of bullion were sold at the smelter for \$50,653, or approximately \$18 gold per ounce. This is a trifle over \$1 gold per yard. The dredgemaster's report covers the period from May 23 to December 26, 1908, and the bank's statement covers the period from June 15, 1908, to January 1, 1909. The following is the summary of the dredgemaster's weekly reports covering the period referred to:

| 1908. | Actual | Bank meas- | | |
|--------------------------------|-----------|------------|----------|----------|
| Week | dredging | urements, | Yards | Repairs, |

The company was established in 1907, with a capital stock of £10,000, and its shares are quoted at £1 10s. No dividends have yet been paid, but for some time its success has seemed assured.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL AND GAS LEASE—FORFEITURE.

An oil lease provided that it should be void if a well was not completed, or in lieu thereof money paid, within a given time. And where the lessor by his conduct clearly indicated that payment would not be demanded when due, and thereby lulled the lessee into a feeling of security, and because of this he did not make payments when due, the lessor was not permitted suddenly, without demand or notice, to declare a forfeiture. In such case a forfeiture will be deemed waived by any agreement, declaration, or course of action on the part of the lessor, which was sufficient to lead the other party to believe that a forfeiture would not be incurred.

Pyle v. Henderson, (W. Va.) 63 Southeast. 762, Jan. '09.

PURCHASER OF MINING CLAIM—NO RESCISSION FOR FRAUD.

The purchaser of mining claims was not entitled to have the contract rescinded on the ground of false representations made by the vendor, where the deal was not closed until three months after the purchaser sent mining experts to examine the property, thereby giving the means of readily acquiring knowledge of the alleged falsity of the representations.

Mitchell Min. Co. v. Hammond, (Ariz.) 100 Pacific 695, March '09.

INJUNCTION TO PREVENT MINERAL DEPOSITS IN STREAMS.

The owner of arid agriculture lands, who has a right to use the water of a river for the purposes of irrigation, has such an interest in the water different from that of the general public, as entitled him to maintain an action to restrain a mining company from throwing its deposits of mineral refuse in streams tributary to such river which would render the water unfit for use.

Arizona Copper Co. v. Gillespie, (Ariz.) 100 Pacific 465, March '09.

QUIETING TITLE TO MINING CLAIMS.

The holder of an equitable title to land cannot sue to quiet title against one holding the legal title; accordingly where mining claims were sold to satisfy liens to a trustee for the lienholders, a purchaser of the interest of one of such lienholders, under an execution, could not sue to quiet title against a person claiming under a deed from the trustee.

Buchner v. Maloy, (Cal.) 100 Pacific 687, Feb. '09.

MINING CLAIM—QUIETING TITLE—COMPLAINT.

A complaint in an action to quiet title to a mining claim was held sufficient where it alleged, in substance, that the complainants were the absolute owners against every one except the Government, of a certain mining claim, by deed, from the original locator, and referring to the location notice as a part of the complaint, giving the book and page of its record in the recorder's office in the county.

Clason v. Matko, (Ariz.) 100 Pacific 773, March '09.

MINING CLAIM—PERFORMANCE OF ASSESSMENT WORK.

The payment of a large sum to persons employed in good faith to perform assessment work on a mining claim, was insufficient to prevent a forfeiture for non-performance of such work, where such person did no more than enter upon the ground and make a pretense of doing the work.

Protective Mining Co. v. Forest City Mining Co., (Wash.) 99 Pac. 1033, Feb. '09.

LOCATION OF MINING CLAIM—RECORDING NOTICES.

The United States statutes specifying the requirements of records of mining claims does not require the recording of location notices; this matter is left to local legislation or to regulation by the miners.

Sturdevant v. Vogel, 167 Federal 448, Feb. '09.

COMPANY REPORTS.

WAIHI GOLD MINING CO., LTD.

In the course of 15 years the dividend distributions by the Waihi Gold Mining Co., Ltd., have been on an ascending curve. The first dividend in 1893 was at the rate of 3s. per share, and amounted to the modest sum of £22,500. The growth has been notable; in 1908 the distribution was at the rate of 17s. per share, or £421,520. An income tax of £32,537 was paid also. The total dividends declared during the life of the mine have reached the grand total of £3,114,794. The bullion return for 1908 was £930,511, representing recovery from 393,214 tons, or \$11.47 per ton in terms of United States currency. Turning back to 1892, in the infancy of the company, we find an output of £46,219 from 20,492 tons, of \$10.65 per ton. Thus has the average been steadily maintained at approximately \$11 per ton, not only showing a remarkable deposit which could permit of such a record, but also a capable management that finds and adheres to a feasible average value of ore sent to mill. An examination of the mine output reveals the care taken to achieve this result. Stopping has been conducted at 40 different places on 9 different levels, in 12 mines of the group. In the Waihi mill 123,182 tons were treated, in the Victoria 264,667, and in the Union 28,982. The total extraction obtained during the year was 90.4% of the gold and 73.3 of the silver contents, representing a gain over the results achieved in 1907 of 1.4 on the gold-extraction, and 3% on the silver. All the concentrate from the three mills is treated in a special plant at the Victoria mill. A total of 6061 tons was handled, assaying:

| | Gold | | | Silver | | |
|------------------|-------|------|-----|--------|------|-----|
| | oz. | dwt. | gr. | oz. | dwt. | gr. |
| Heads | 5 | 10 | 19 | 65 | 19 | 0 |
| Tailing | 0 | 4 | 3 | 4 | 12 | 23 |
| Extraction, %... | 96.28 | | | 92.95 | | |

The milling is done with a total of 330 stamps, and 10 tube-mills. The average duty per stamp was 4167 tons per diem, representing an increase of 0.373 ton per stamp over the duty in 1907. As no details of the stamp-mill practice are given, nor any record of stamp-horag kept, closer analysis is impossible. The tube-mill plant, together with the vanners, and three elevator-wheels, are driven by three 200-Crossley gas engines. It has been found inadvisable to run more than three tube-mills with each engine. These engines are actuated by producer gas made on the premises. No trouble has been experienced with any part of this power plant, aside from the breakage of two engine crankshafts during the year. The costs of operating amounted to £381,392, or approximately \$4.74 per ton. Mining costs, including development, reached \$1.89 per ton. The development was 17,320 ft., of which 4286 was in cross-cuts through the country. Minute details of the separate items of expense are lacking, rendering close examination difficult. It may be well, however, to point out that the costs of crushing and milling were only 70c. per ton; metallurgical treatment (extraction) \$1.02; assaying and melting 10¼c; repairs and renewals, 10c.; salaries of local staff 9½c. The company affirms that it has reached the limit of commercial efficiency with the present plant, and that any increase in the percentage of extraction results in a loss. The pumping capacity at the mine has been increased by the provision of two 750-hp. gas producers, and two 368-hp. gas engines, and two electrically driven three-plunger pumps with a capacity of 1500 gal. per minute. The power plant will be erected at No. 5 shaft, and when the electric pumps are not in use the power will be applied in driving air-compressors and other machinery at No. 5 shaft. As soon as a demand is made on the pumping plant the power will be diverted to No. 7 shaft for the time being.

In June 1908, the Waihi Workmen's Union made demands in reference to a system of contracting, and a strike was averted only by the exercise of great tact. A more serious trouble arose in January. By the operation of a new Act certain heavy liabilities were imposed on mine-owners on account of pneumo-coniosis, or, as it is currently termed, 'miner's disease', being an affection of the lungs due to dust.

ELECTRIC-DRIVEN WELL-DRILLER.

Written for the MINING AND SCIENTIFIC PRESS
By J. VALE DOWNIE.

There has been some demand for a portable blast-hole drilling-machine operated by an electric motor instead of by a boiler and engine. Where blasting operations are conducted within the city limits, some inconvenience, and a large item of expense, are represented in providing a licensed engineer, as required by law, for each separate steam-driven machine. There is also economy in generating all power at a central plant. In some situations it is impossible to use the boiler. To avoid this some contractors have operated a series of machines from one centrally placed boiler, carrying steam-lines to the several machines. Some have used compressed air in the same way, as was done in the extensive blasting operations on the low grade cut-off of the Pennsylvania railroad. But this involves the constant re-laying of steam or air-lines, with bother and loss of power from condensation, leakage, and the like. The motor-driven drill was designed to obviate these and other disadvantages connected with the steam machine as used on certain classes of work.

The Keystone electric-driven machine recently tried at the James & A. C. O'Laughlin quarry, at Belwood, near

Keystone Electric Well Driller Showing Motor Box.

Chicago, was equipped with a 10-hp. specially geared motor, placed over the rear truck of the machine, and belted to the drilling mechanism. (See Illustration). The drilling-mechanism is back-geared, and balanced so as to run light and smoothly. The controller-box is placed at the drill-operator's hand, in front, as shown in the illustration, along with the other levers which regulate and control the various operations of drilling. The manipulation of the motor is simple, and the ordinary drill-man will become thoroughly competent to handle it with a few minutes' instruction from the electrician. The laying of feed-wires and other like adjustments will be looked after by the electrician in charge. One man can easily handle the machine without assistance, except when sand-pumping or moving the rig to a new hole. This is another saving on the cost of operating the steam-machine, which requires the constant attention of a fireman, besides the driller. The motor, drilling-mechanism, derrick, etc., are all unified in a machine which is moved from hole to hole in its entirety. For short moves the derrick is not taken down.

At full speed of the motor the drilling tools drop about 60 strokes per minute, which is ample in all cases to obtain the maximum drilling speed. As the hole becomes deeper or clogged with cuttings, before sand-pumping, the rapidity of the stroke is gradually reduced to say 50 strokes per minute, in order that the cutting bit may deliver its blow with best effect. This can be done by reducing the speed of the motor. The drilling tools used

with this outfit comprise a stem, weighing about 1000 lb., drill bit of 150 lb., and rope-socket of about 50 or about 1200 lb. in all. The bit cuts a 5½-in. hole and the stem is 3¾ in. diam., and 22 ft. long. The stroke being from 30 to 36 in., a blow equal to about 3000 to 3500 foot-pounds can be obtained at each stroke. This is sufficient to cut a 5½-in. hole very rapidly through any formation.

Best results have been obtained, in blast-hole drilling, with the 5½-in. hole. This size obviates the necessity of 'squibbing' charges which must be employed in the smaller holes. It is also more easily and cheaply drilled than a hole of larger or smaller diameter. The larger hole involves more cutting while permitting no corresponding advantage in size and weight of drill-bar; the heaviest practicable tools can be operated in the 5½-in. hole. On the other hand a smaller hole necessitates a reduction in the diameter and weight of the stem and bit, which detracts from their efficiency. It has been proved experimentally that a 6-in. hole can be drilled more quickly and cheaply than a 3-in. hole.

The results of the test at the O'Laughlin quarry were as follows: The machine was set up Saturday evening, June 5, 1909, at 5 o'clock, and began drilling. It was operated for one hour, during which 9 ft. were drilled in fairly hard limestone. From this time until the following Friday forenoon four 66-ft. holes, 5½-in. diam. were drilled, the

Keystone Drill Showing Controller Box at Driller's Hand.

work being done without a hitch, and without the necessity of any change whatever in the machine. In the following week were drilled four holes 105 ft. in depth, the machine running 10 hours per day in all cases. The record of a similar machine at Racine, Wis., in slightly harder rock was 900 ft. in 200 hours, including all stops and delays in moving the machine.

This is a remarkably successful test, and a very satisfactory demonstration of the practicability of electric-driven well-drills. The machine was more or less of an experiment, nothing of the kind having been tried before.

The Keystone Driller Co. had guaranteed the machine to drill to a depth of 60 ft. at the rate of 40 ft. per day of 10 hours, or 4 ft. per hour. The purchasers of the outfit now state that it is drilling 5 ft. per hour, including all stops, which must be regarded as a very good showing in hard rock. This is probably equal to the results obtained with the best steam-machine, under the most favorable circumstances. The advantages of the steam-machine in variability of speed and reversibility of engine seem to be not very great. This machine is built with gear-hoist, capacity 500 ft., or with friction-hoist, capacity 350 ft. The latter style is probably the better for quarry and cut-drilling, where the tools are being constantly raised and lowered, as in tamping a charge. One driller reports that he raised and lowered his tools 900 times in one day, when tamping dynamite charges in four holes. The holes will rarely run over 150 ft. in depth. The machine is also made with traction attachment, for self propulsion, and,

while it is impracticable to move it over great distances, on account of carrying along the electric feed wires, for short moves from hole to hole, or from one side of the quarry to the other, it is a great advantage. The delay in waiting for a team of horses is saved, as well as the expense. For short moves the self-braced derrick is left standing.

The advantage of large deep blast-holes in saving 'squibbing' charges has been referred to. Another advantage is that the holes can be sunk from the surface to a point a little below the base of the breast, no matter how high the face of the quarry. A heavy charge is then placed at the bottom and the whole breast is lifted out at one discharge, without the necessity of stoping and cleaning up at various levels. From the simultaneous discharge of 4 holes, 5½-in. diam., and 66 ft. deep, the manager of the quarry states that 20,000 cu. yd. of stone were thrown down by one shot. The explosive consisted of dynamite to the amount of 5500 lb. packed solidly in the holes to within 25 ft. of the top, and tamped with screenings. The blast is made much more effective by drilling the holes properly. The large holes allow the powder to be well bunched at the bottom. Generally the machine is used for loading the holes. For this service the regular drilling-bit is removed, and in its place a wooden rammer is placed on the drill-stem. Five to eight sticks of dynamite having been dropped into the hole, the drilling tool is lowered after them, forcing them into a compact mass at the bottom. The tools are then withdrawn, and the process is repeated until the hole is filled to within 25 ft. of the surface. At this point the exploding caps and wires are inserted, and the holes are packed full of sand and gravel to the top, by hand.

Some conception of the quantity of material thrown out by such a blast may be gathered from the effect of one shot in the O'Laughlin quarry. From the base of the breast to the edge of the débris was a distance of about 200 ft. The breast was 105 ft. high. For this shot the holes were put down only half way, though the engineer in charge states that they might as well have been sunk to the bottom, and in the future this will be done. In this case there were a few large chunks in the débris which will have to be drilled and blasted; but nearly all was in condition to be handled by the steam-shovel and taken at once to the crusher.

THE total production of coal in West Virginia in 1908, as reported to E. W. Parker, of the U. S. Geological Survey, was 41,897,843 short tons, having a spot value of \$40,009,054. Owing to conditions more favorable for the cheap production of coal in West Virginia, her percentage of decrease during 1908 was less than in Pennsylvania, Maryland, Alabama, and Ohio. The decrease was 6,193,740 short tons, or 12.88%, from the output in 1907. The decrease in Pennsylvania (bituminous coal) was 21.95%, in Maryland 20.89, in Alabama 18.57, and in Ohio 18.27. The decrease in value of the production in 1908 was \$7,837,576, or 16.38 per cent.

ALABAMA'S coal production in 1908, as reported to E. W. Parker, of the U. S. Geological Survey, was 11,604,593 short tons, having a spot value of \$14,647,891. The effect of the business depression was exhibited by a decrease of 2,645,861 short tons, or 18.57, in quantity, and of \$3,757,577, or 20.42%, in value, as compared with the output of 1907. Nearly half of the decline in production was in the quantity of coal made into coke, this item having decreased from 4,973,296 short tons in 1907 to 3,857,791 short tons in 1908.

CHROMITE of chromic iron ore production is an industry of minor importance in the United States, owing to the small extent of the deposits. According to a report by E. C. Harder, just issued by the U. S. Geological Survey, the maximum output was reached in 1894, when the production was 3680 long tons. In 1908 but 359 tons, worth \$7230, was produced, mostly in California. The imports of chromic ore in the same year were 27,876 tons, mainly from New Caledonia, Greece, and Canada.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ANNUAL REPORT OF THE MINISTER OF MINES FOR 1908, IN BRITISH COLUMBIA. Pp. 269. Ill. Victoria, 1909.

This is a well prepared, well printed, well bound summary of current mining operations in the Province. It contains excellent statistical data, the reports of the various gold commissioners, summary statements regarding mining operations, lists of certificates of competency issued by the Bureau of Mines, and miscellaneous reports by the Provincial Mineralogist and by members of the Geological Survey of Canada. British Columbia has a total recorded mineral production of \$323,377,559, of which \$23,851,277 was produced in 1908. The largest single item in the total production is gold, which has amounted to \$70,196,103 from the placers and \$50,353,597 from the lodes.

FLUOSPAR DEPOSITS OF KENTUCKY. By F. J. Fohs. Kentucky Geological Survey, Bull. 9, Pp. 296. Ill. Index. Lexington, Ky., 1909.

This report is of the excellent type where the author not only gives the details regarding the local deposits, but summarizes existing information relating to the material elsewhere. The occurrence, production, technology, and market conditions are all discussed. In view of the tariff just put on fluorspar the report is especially timely. There is opportunity for considerable expansion of the fluorspar industry in America, and Mr. Fohs' report is the only complete work available. It will undoubtedly prove widely useful.

INDEX OF MINING ENGINEERING LITERATURE. By Walter R. Crane. 8vo. Pp. XII. 812, Index. John Wiley & Sons, New York, 1909. Price, cloth, \$4; morocco, \$5.

This book has been prepared as a result of the author's own needs through a series of years, and is intended to cover mining, metallurgical, civil, mechanical, electrical, and chemical engineering subjects as related to mining. The material has been roughly classified under various subjects, from accidents, to water, and under each heading there is a secondary classification, but beyond that there seems to be no special order. The book will serve a useful purpose.

IRON ORES OF NOVA SCOTIA. By J. E. Woodman. Dept. Mines, Mines Branch, pp. 226, Ill., Maps. Ottawa, 1909.

This is the first part of a report based on surveys begun in 1906. It covers the geographic relations of the deposits, the geology, an account of titles and bounties in the Province, a brief description of costs and labor conditions, and detailed descriptions of the deposits in eight of the districts.

REPORT OF THE NATIONAL CONSERVATION COMMISSION. Pp. 52. Bull. 4.

Issued by the Joint Committee on Conservation, Washington, 1909. Containing the report of the Commission and a history of the conservation movement.

MINING AND QUARRY INDUSTRY OF NEW YORK STATE. By D. H. Newland, New York State Museum, Bull. 132. Pp. 99. Albany, July 15, 1909.

Detailed report on the operations and production during 1908.

ARTIST OR ARTISAN—WHICH? By Victor C. Alderson. Quarterly. Colorado School of Mines. Vol. 4, No. 1, July 1909.

Commencement address, South Dakota School of Mines.

PETROLEUM AND COALS, COMPARED IN THEIR NATURE, MODE OF OCCURRENCE AND ORIGIN. By Eugene Coste. Canadian Mining Institute, Vol. 12, pp. 29. Ottawa, 1909.

YEAR BOOK OF THE MICHIGAN COLLEGE OF MINES, 1908-1909.

Commercial Paragraphs.

THE WOOD DRILL WORKS of Paterson, New Jersey, are distributing their monthly circular, No. 47, giving a review of work on the Tieton Project, U. S. Reclamation Service. It can be procured from any of the American sales offices.

EDITORIAL.

AS a first answer to protests against the restriction of code-words to five letters, the telegraph companies have suspended the application of the new order until December 1. If the initial growl with which the order was received be continued the 'suspension' will become permanent.

THE WAIHI Gold Mining Co., Ltd., now has liquid assets of over two million dollars. Each year approximately 10 per cent is written off for depreciation, so that now the book value of the property, which cost \$5,000,000, is \$1,800,000, while the market value is \$22,000,000. The conservative management of this great property affords many a lesson.

Phases of the Mexican Situation.

Americans in Mexico are organizing committees to protest against the exaggerations of the daily press in this country which find capital for sensationalism in the political ferment over the approaching elections. These protests cannot fail to make an impression upon thoughtful people on this side of the Rio Grande. Impressive also are the activities of the Pearsons and the Southern Pacific in railroad building, and the conclusion of such transactions as that which resulted in the purchase of the La Blanca mine at Pachuca the other day by capitalists led by Mr. John Hays Hammond. It is doubtful whether foreign capital has ever been poured into Mexico so abundantly at any period in her history as during the past six months. The political agitation has been at bottom a protest against the liberality of the Government in granting concessions and in favoring foreign corporations in ways which have given them an advantage over domestic companies. This has furnished a motive for raising the popular cry of 'Mexico for the Mexicans', and such a sentiment naturally opens an opportunity for demagogues. Government cannot turn a deaf ear to such appeals, in Mexico or in any other country. To do so is to invite political embarrassment. It is not surprising, therefore, to note that Señor José Yves Limantour, the Secretary of Finance, has requested a more rapid advancement of Mexicans in the railway service, and that Señor Olegario Molina, who holds the portfolio of Fomento, has placed limitations through the mining regulations upon new business undertaken by foreign corporations. The revised mining law has not yet become operative, and it is hinted that some restriction, similar to that now put into force, will be incorporated in the final Act. This, however, will not affect corporations protocolized under the old law, and will not preclude absolute control of new operations through the ownership of Mexican

corporations by aliens or by foreign companies. It is only a sop to the multitude to appease a popular demand in the interest of political calm.

Classification of Public Lands.

The address delivered before the Irrigation Congress by Mr. George Otis Smith, Director of the United States Geological Survey, and published in the MINING AND SCIENTIFIC PRESS, August 14, will warrant a careful reading. There are wide-spread misconceptions regarding the means by which the public lands are classified. At the Trans-Mississippi Commercial Congress at Denver last week an entire session was devoted to debate upon a resolution proposing that a commission be established to make "topographic and economic" surveys of the National Forests, and to recommend to President Taft for elimination all lands more valuable for mineral or agricultural than for forestry purposes. The chairman of the sub-committee on resolutions, Mr. Charles F. Potter, stated that no authority now existed in law for making such surveys, and the mover of the resolution, Mr. T. M. Patterson, hailed the proposal as something new and as affording the only satisfactory solution of many vexed problems. As a matter of fact, both gentlemen were evidently ignorant of the present provision of the United States statutes, and also of work which has been going on for a number of years. One of the duties given to the United States Geological Survey when it was established in 1879 was the "classification of the public lands," and since the first field-season "topographic and economic" surveys of the public lands have been made. For a number of years there has been a specific appropriation for topographic surveys in the Forest Reserve, and large portions of the Forests have been so surveyed. On the field-sheets of these surveys the character of the land, whether agricultural, wooded, mineral, arid, or watered, is indicated. These reports are supplied to the Land Office and to the Forest Service, and selection of lands for withdrawal from entry or for elimination from the Forests, is based on these maps wherever available. That only parts of the Forests have been surveyed is due to the rapidity with which the reserves have been created, and the limited appropriations made for work. Two years ago the appropriation was reduced, neither Mr. Patterson nor Mr. Teller, at that time in the U. S. Senate, who are now so active in demanding that the surveys be made, entering any protest.

There is no question that in the National Forests as now delimited, lands have been included which might well be withdrawn. The boundaries were determined as accurately as existing maps permitted, and the President has now authority to exclude from the Forests any lands found to have been wrongly included. Such lands are now being constantly thrown open to entry. On the other hand, no additional lands can be included in the Forests except by Congressional action. In view of these facts, it is not clear what good purpose would be served by creating a new commission to undertake work already being done by warrant of law by a well-organized and

capable bureau. The need is rather for strengthening existing agencies. No good can come from a hurried and imperfect survey. If the public lands are in each case to be put to their highest use they must be studied and classified by competent men acting on the basis of adequate data. More and more it is becoming apparent that much of the present friction between the Government and individuals over the entry of lands is due to imperfect classification.

Gasses from Explosives, and Mine Economy.

Few details of mine management offer larger opportunities for improvement than the use of explosives. Pride in betterment of technical operations has stimulated workmen in almost every branch of mining, with this exception. Attention to the subject of blasting has been forced upon coal miners, on account of the peculiar perils presented by an atmosphere liable at any time to contain explosive mixtures of gas and air, but the metal miner has been suffered to pursue unrestricted whims. The result is an economic waste attaining great aggregate magnitude. Not only is powder applied inefficiently, but the imperfect combustion of the explosive results in vitiating the atmosphere in the mine with carbon monoxide, an active poison. Thus the health and efficiency of the workmen are impaired. The demands of miners for better ventilation are becoming more insistent, but there is manifest folly in deliberately fouling the air and then providing means for overcoming the damage done. It reminds one of taking a poison in sheer wantonness only to follow it with an antidote. In the Rand gold mines of South Africa the question of gases from high explosives is receiving critical attention. Elsewhere in this issue we publish results of researches made by Mr. William Cullen to determine the quantities of carbon monoxide produced in the detonation of gelatine dynamite under various conditions, which lead him to declare that large volumes are always evolved in ordinary practice, the actual amount present in the air near the end of a closed drift after blasting being approximately one per cent, and the ratio between the CO and CO₂ being about one to eight. In view of the fact that theoretically under ideal conditions the combustion should be so perfect as to yield no carbon monoxide at all, and as the ratio between the calorific intensity of combustion yielding CO and CO₂ is as 1 to 3.26, it is seen how great is the waste of explosive when imperfect detonation occurs.

The work of Mr. Cullen does not seem to us conclusive, although it is immensely suggestive. There are many factors entering into the efficient detonation of dynamite and blasting gelatine which he fails to take into account in his experiments. The use of tamping is undoubtedly beneficial, and clay is better than sand or loose earth. Nevertheless, the importance of tamping decreases with the violence and suddenness of the detonation; in other words, the greater the velocity of the detonating wave, the more perfectly is the inertia of the air realized as a sufficient resistance to prevent relief of pressure through the drill-hole. As a matter of fact, however, the

suddenness of the detonation is never sufficient in ordinary practice to enable the operator to dispense with tamping. Homogeneity of the charge is a still more important consideration. We are inclined to attribute imperfect detonation more to lack of this than to any other cause. The higher the velocity of the detonating wave the more perfect will the combustion be; any alteration in the velocity of transmission of this wave through the charge results in inequalities of combustion which means an increase in the percentage of carbon monoxide, with a corresponding diminution in the expansive effort of the resultant gases. Our Johannesburg correspondent this week refers to a new mixture, with gelatine dynamite as a base, lately presented by Mr. Cullen, intended to prevent the formation of obnoxious fume. It is unfair to offer criticism upon this suggestion, but unless an explosive be properly used nothing can alter the fact that efficiency is lowered thereby, and carelessness in charging holes would seem to be encouraged in proportion as men are relieved from injurious consequences of neglect. In common 50 per cent dynamite as manufactured in this country today, an excess of over 6½ per cent of available oxygen is provided in the mixtures. That is certainly ample to insure complete combustion under intelligent use, but when miners place a primer in the middle or at the bottom of a charge, when the powder is not carefully pressed in, when weak detonators are employed, and when these are inserted without regard to perfect contact with the explosive, an excess of oxygen will not prevent imperfect combustion of the powder. It is impossible to secure more than an approximation to ideal conditions, but certain patent errors in manipulation can be avoided, and the efficiency of the explosive increased. It would be interesting to obtain data concerning the amount of explosive consumed in mining under various conditions, but these facts seldom appear in company reports. In some mines the amount used in stoping is as low as a half pound per ton of ore; in others it amounts to several pounds. There are probably few mines in which it might not be greatly reduced, and every quarter pound per ton, at an average price of 12 cents, at a mine producing 1000 tons per day, would involve a saving of over \$10,000 per annum, accompanied with improvement in the health of the men employed underground.

Metal Markets and a Merchant Marine.

A popular impression exists that the new tariff law re-establishes a discriminating duty between goods imported in foreign and American vessels. This, however, is neither new nor will it be effective. It was by a differential duty of 10 per cent, favoring imports in American ships, that the maritime commerce of the United States invaded all corners of the globe in the early days of the Republic. Concessions were then made, under pressure from other countries, by treaty and by statute, destroying this eminently protective advantage. Those disabilities still exist, and the present law, after making its empty affirmation, adds that this "shall not apply to goods, wares, and merchandise which shall be imported in vessels not of the United States, entitled at

the time of such importation by treaty or convention or Act of Congress to be entered, etc., etc." This was also stated in the Dingley bill in similar terms. Congress is powerless to write an effective law of this tenor into the statutes. That is the humiliating fact; and an administration that would pretend to pave the way for such a regulation by diplomacy would need a bigger navy than we now possess in order to give convincing force to its remarks, else it would stultify itself as President Polk did playing Bombastes Furioso with his futile 'Fifty-four Forty or Fight'. Mr. A. H. Barchfeld, representative from Pennsylvania, at an after-dinner speech in San Francisco, Monday night, informed his fellow banqueters that President Taft and the potentate of the House of Representatives authorized him to say that the sixty-first Congress will enact a ship subsidy bill that will create a great merchant marine, giving us commercial control of the seas. We suppose Speaker Cannon actually can achieve it if he wishes; and Mr. Taft could help. Then there would be no need for writing an apology after the signature. Whenever the steel trust is willing we can have a merchant marine. Mr. Cannon knows Judge Gary's mind on that point. Let us hope Mr. Barchfeld knew what he was saying, even if we do have to pay the steel magnates 'both going and coming', as the phrase is.

The control of ocean-borne commerce means control of the metal market of the world, which will give smelter's profit as well as banker's toll. In the aggregate this involves one of the largest commissions to be taken from the conduct of international trade, and it would bring to this country a profit which would overtop the cost as the Sierras tower above the foothills. The mining industry has a legitimate interest in the development of a merchant marine. It will enlarge the volume of the smelting business in America, will provoke keener competition, and will provide cheaper rates for treatment, to say nothing of the expanded market abroad for metals and metallic manufactures. An accessible world-market is as much better for controlling and steadying demand and price, as the Great Lakes are more efficient in regulating floods than is the Tensas basin for a fluctuating Mississippi. To merely spill over into foreign trade when times are flush does not give that stability which comes from the vital relations which are brought into being through a great merchant marine and the foreign commerce it creates. With such a stimulus the mines of America would not suspend as they did a year and a half ago.

If we may not apply the principle of discriminative duties perhaps we can pay a bounty on importations in American bottoms. Each country has its own peculiar boggy; Canada shrinks from increasing the tariff on iron and lead, but pays bounties without a shudder; the Americans adjust themselves to the burden of high customs duties as a pack-mule to his load, but take fright at an open payment of cash for the encouragement of industry. "What's in a name?" What matter whether we call the same thing bounty or protection, so long as it gives us strength?

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. H. CURLE is in Norway.

P. GEORGE GOW is in Scotland.

HENRY KRUMB is at Ray, Arizona.

H. F. COLLETT is in San Francisco.

LEON DOMINIAN has gone to New York.

ANDRÉ P. GRIFFITHS was in Paris lately.

WALDEMAR LINDGREN is in San Francisco.

W. P. GRIGSBY has gone to Goldfield, Nevada.

T. S. MATHIS has gone to Hanover, New Mexico.

F. E. ROCKWELL has gone to Floyd Hill, Colorado.

JUSTIN H. HAYNES has gone to Telluride, Colorado.

ALWYN C. SMITH has returned to Golden, Colorado.

W. J. BARNETT has returned to London from Siberia.

C. H. GRIFFEN, Jr., has returned to Berkeley, California.

ALGERNON DEL MAR has gone to Sutter Creek, California.

A. E. DRUCKER has been in Kalgoorlie, Western Australia.

E. C. LIMBACH has removed from Seattle to Loomis, Washington.

THEODORE J. HOOVER has returned to London from the Caucasus.

L. K. FLETCHER has left Salt Lake City and is now in San Francisco.

THOMAS NUTTALL MILLER has returned to Douglas City, California.

RALPH C. NOWLAND is spending a few weeks at Spokane, Washington.

W. A. KUNKLE has left Indé, Durango, and is now at Aspen, Colorado.

W. H. GARLICK has gone to Easton, Maryland, from Ontonagon, Michigan.

F. F. KETT has left Berkeley to go to the Braden Copper Co. at Graneros, Chile.

N. H. EMMONS has become general manager for the Tennessee Copper Company.

A. SONSTHAGEN has gone from Terrazas, Chihuahua, to Orogrande, New Mexico.

W. B. MCPHERSON has returned from Las Baños, California, to San Francisco.

J. V. BOHN is general superintendent of mines for the Tennessee Copper Company.

JOHN H. EGGERS has gone to San Sabastian, Jalisco, Mexico, from San Francisco.

FOSTER HEWETT has been in South Pass, Wyoming, Wallace, Idaho, and Butte, Montana.

FREDERICK H. MORLEY has gone to Chihuahua. He will return to Denver about September 15.

STANLEY N. GRAHAM has returned to Kingston, Ontario, from Hostotipaquillo, Jalisco, Mexico.

T. M. LOWRY, Government Inspector of Mines in West Africa, is in England on leave of absence.

W. BROADBRIDGE has arrived in London from West Africa, but he is returning thither immediately.

BENJAMIN LE ROY MILLER and J. T. SINGEWALD, Jr., of South Bethlehem, Pennsylvania, were in San Francisco.

G. E. KEDZIE has left the Ventanas mine at Chavarria, Durango, and is at present in the city of Durango, Mexico.

E. H. WEBSTER has left the Fianza Mining Co., Guanaceví, Durango, to become resident manager of the República mine, Ocampo, Chihuahua.

THOMAS COX has sailed from Perú for New York. He will reside in San Francisco. The firm of Cox & Juessen will specialize in the design of mining, milling, and smelting plant.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Denn-Arizona Copper Co. has started sinking from the 1250-ft. level. The ore here is mixed sulphide, oxide, and some native copper, and it is hoped to reach the sulphide zone at the 1500-ft. level.—The adit on the Doran & Gallagher group cut a 10-in. vein of lead-silver ore. The north cross-cut from the 120-ft. level has been started and has cut several small bunches of copper ore.—The first shipment of ore from Courtland over the Mexico & Colorado railroad went to Douglas August 17. Since that time from two to six cars per day have been shipped. From Douglas the ore is shipped over the El Paso & Southeastern tracks to the El Paso smelter.—Work has been suspended at the Germaine shaft of the Calumet & Arizona company to install a new boiler and pump. A good tonnage of ore is blocked out here and stopes will be started as soon as a switch to the mine is completed. George A. Arnold is manager. At this company's smelter the old furnace is being re-modeled, and when completed will have a capacity of 500 tons per day. The plant will then consist of three 500-ton and three 300-ton furnaces.

GILA COUNTY.

Samples from the 700-ft. drift of the Lost Gulch United Mines Co. in the Globe district assayed as high as 9% copper and \$100 gold per ton. The old quartz mill which was built by former owners of the property is being dismantled.—The Sullivan shaft at the Cordova mine opened a body of copper glance at a depth of 360 ft. The glance is in a gray schist similar to that found in the Miami and Inspiration properties.—During September the Arizona Commercial Copper Co. will commence shipping. The management expects to produce about 1,000,000 lb. of copper per month.

MARICOPA COUNTY.

J. W. Witherlay and associates have purchased the Golden property near Wickenburg. The building of the railroad through that portion of the country will reduce freight rates and is hoped will put the mine on a paying basis. Some high-grade gold ore has been taken out in the past.

PINAL COUNTY.

The Ray and Gila companies have closed their experimental mill at Ray and no more ore will be treated until the new plant is finished. The structural steel should be on the ground by September 1 and the work of construction started by the 15th of that month.

YAVAPAI COUNTY.

The Arizona Copper-Gold Mining Co. shipped a \$500 gold-bar as the result of a test run of the Lane mill recently installed at this company's plant on Cherry creek. The foundation was not heavy enough to stand the vibration and is being replaced.—The owners of the Mirably mine on Groom creek have leased a 5-stamp mill and will crush 50 tons of ore which they have on the dump. The vein which is from 12 to 20 in. wide has been cut by a 325-ft. adit and a drift driven along it for 150 ft. Average samples run \$35 per ton.—Operations have been suspended at the plant of the Octave Gold Mining Co. at Octave to install new machinery that will increase the capacity of the plant 25 per cent.

YUMA COUNTY.

The Yuma Copper Co. has been incorporated to continue development on its property in the Harecuvar mountains. There has been approximately \$40,000 spent on the property and some good copper ore opened.

CALIFORNIA.

ELDORADO COUNTY.

Some excellent ore is being opened by the drift on the 300-ft. level of the Mt. Pleasant mine at Grizzly Flat.—The shaft at the Morey property is down 50 ft. in ore.

INYO COUNTY.

The Casa Diablo Mining Co. has completed the installa-

tion of two carloads of mining machinery and has ordered two Leyner drills and a Leyner drill sharpener.—King brothers are to start their mill on ore from the Unthank lease on the St. Ives ground shortly. There is about 300 tons of \$15 ore and 40 tons of \$40 ore on the dump. The vein is from 12 to 18 in. wide in the bottom of the 125-ft. shaft.

MARICOPA COUNTY.

The owners of the Hite mine at Hite's cove are building a wagon-road from the mill to South Fork, the station on the Yosemite railroad. The road will be through a hard country to build in, but it will reduce the freight rates enough to warrant the expense. The Hite mine is an old one with a good record in the past, and with the wagon-road completed and new machinery installed should be a steady producer for a long time.—The South Fork Mining & Power Co. has a crew of surveyors at work running the lines for the ditches and dam at its water-right near Peach Tree.—The Trujillo Mining Co. has just completed its mill on Grizzly flat. C. G. Lewis is manager.

MONO COUNTY.

The Sierra Oil Co. has erected a derrick on the northwest side of Mono lake and started drilling for oil. The machinery is capable of drilling to a depth of 5000 ft., although it is anticipated that the oil-bearing shale will be cut before that depth is reached. Harry Soderberg is superintendent.

NEVADA COUNTY.

The cross-cut from the lowest level of the shaft at the Union Hill mine near Grass Valley cut the vein 700 ft. below the outcrop. This gives 300 ft. of backs on this vein, and the cross-cut will be driven to open several veins known to exist beyond this. It is the intention of the company to add 20 stamps to the mill. C. J. Graham is superintendent.—A shoot of rich ore was cut by the lower adit of the Red Ledge mine near Washington.—The 30-stamp mill, hoisting plant, and compressor house at the Eagle Bird mine near Maybert were completely destroyed by fire. W. M. Wilson, the owner, estimates the damage to approximate \$40,000.—Some excellent specimens of copper ore have been taken from the claims of Otto Woehler near Spencerville.—The North Star Mines Co. has purchased the stock of the Grass Valley Mining & Milling Co., which controls the Hermosa mine. The property has been idle for a number of years.—C. L. Wilson has bonded the Gregory group of claims, two miles from Moores Flat. There are nine claims in the group, which is situated in the southern portion of the Alleghany district.—The Eastern people who recently bonded the Red Cross mine near Omega have ordered a Huntington mill and will have it installed in a short time. A rock breaker is now being installed at the mine.—At the Oustomah mine a cross-cut is being driven from the 1050-ft. level to cut the vein.—The Dana mine in the Grass Valley district is to be opened. The property was recently bonded to an Eastern firm and the shaft unwatered. The shaft was sunk in an 8-ft. vein and the gold content has been of sufficient value to warrant the company planning more extensive development work.—The German mine in the Washington district has been bonded and a drift started on the vein.

SAN BERNARDINO COUNTY.

The recent negotiations for the sale of the Jumbo mine near Hart have been called off and the mine is again working after a shut-down of 60 days. The Foster brothers and Patrick McCluskey, who own the property are now planning to install a mill and hoisting machinery as an open-cut east of the shaft recently opened 20 ft. of \$30 ore.—The raise in the Oro lease of the Big Chief Mining Co. is up 40 ft. in ore of good milling grade. A 40-hp. hoist is to be installed at the Daton shaft in a few weeks. The shaft is now down 50 ft. and the company will sink to the 100-ft. level and cross-cut.

SHASTA COUNTY.

The Mammoth Copper Co. has added a 12 by 30-ft. experimental reverberatory furnace to its equipment. The object of the furnace is to make tests on the further recovery of

the copper content from the slag. The company is working about 110 men at the Quartz Hill mine and taking out about 300 tons of ore per day. This is in excess of the usual amount and a portion of it is being stored for use this winter. Two men were killed by a cave-in on August 21. The men were running a machine-drill in an untimbered portion of the mine.—Sharp & Todd have a contract to run several diamond-drill holes at the Summit group near Kennett.—The 6-mile spur from the Southern Pacific railroad to the Delta Consolidated mines on Dog creek has been completed and ore shipments will be started to the smelters at Kennett and Coram.—The carload of pig-iron recently shipped from the Noble electric smelter at Heroult to the Northern Engineering Works in Redding has proved satisfactory and is now being made into castings to be used in the Heroult smelter. The plant is running steadily, although some minor changes are still to be made in the machinery. About five tons of pig are being cast per day.—A small amount of paraffine oil was brought up by the sand-pump from the well the Terry Lumber Co. is sinking at Bella Vista. This well is being sunk for water, but a company has been organized at that place to drill for oil.—At a meeting of the Farmers' Protective Association at Anderson a committee was appointed to confer with the managers of the Coram and Kennett plants to see if a satisfactory arrangement could be made with the smelting corporations in regard to the damage done by the smoke to the crops of that vicinity.

SIERRA COUNTY.

At the Alaska mine near Pike City a drift is being driven east on the Contest level to tap the ore-shoots found in the upper workings. The raise in the shoot recently opened continues in a good grade of milling ore and it is expected to open a stope there shortly and start the mill.—The drift at the Oakland mine is in good ore. Frank B. Voyle is the owner.—The churn-drill to sample the old gravel channel in Reese ravine near Downieville has been hauled to the property and will be working in a few days. George McGee has charge of the work.—The adit of the Kieffer brothers at the Gibraltar mine has cut the gravel, but as yet the bedrock has not been reached, so its value is still unknown.—At the Hunch property near Alleghany a cross-cut has been started that will tap the vein at a depth of 100 feet.

SISKIYOU COUNTY.

Crocker & Frenet, of Eureka, are re-opening the Sugar Creek mine.—The lessees of the McKean mine near Calahan are milling some excellent ore.—Fred Dakin has purchased the Dewey No. 3 claim in Happy Camp from I. Hendrickson for \$4000. There is a good showing of copper ore on the surface.—John B. Farish has been examining copper properties in Happy Camp.

TRINITY COUNTY.

James Sallee, former owner of the Iron Mountain and Bully Hill mines in Shasta county, has been examining the Bonanza King mine near Trinity Center for San Francisco interests. The Bonanza King was controlled by men allied with the California Safe Deposit & Trust Co. and has not been active since that institution closed its doors.—The Trinity River Mining Co. has not turned the water through its tunnel, as was expected, owing to delays caused by the late delivery of a portion of its machinery. It is probable the plant will be in operation some time in September.—A. C. Cruchet, of the American Securities Co. of Boston, has obtained an option on the placer ground of G. A. Tinsley and H. W. Hudson near China Flat. A ditch and flume will be constructed and a No. 3 giant installed so the mine will be ready for operation next winter.—The New River Mining Co. is to take over the mining claims of the Noble brothers in the New River district. The first payment of \$1000 is due September 15. Theo. H. Minor is president of the company.

TUOLUMNE COUNTY.

A company is being organized in Sacramento to work the bed of the Tuolumne river below Stevens bar. Several attempts have been made to obtain the gold from the bottom of the river, as it is known to be rich at this point, but the

flow of water has been too heavy for the previous operators to get to bedrock. James Geddes, of Sacramento, is one of those chiefly interested in the enterprise.—The mill at the Street property is running on ore from the Atlas mine.—W. C. Faller, who recently bonded the Dorsey-Newcomer property, opened a rich vein of quartz on Knight's creek.—The Collier & Herbert property in the same district is being unwatered and the owners will deepen the shaft and work the ore as it is taken from the development work. There is an arrastre on the property and a small cyanide plant will be erected shortly. The vein varies from 1 to 2½ ft. in width and mills \$50 per ton.

COLORADO.

CHAFFEE COUNTY.

The new Kuenzel smelter at Buena Vista is running successfully on the ores of that district. Two cars of ore that ran \$86 per ton were shipped by Thorndale & Helman from the Decorruk mine to the smelter. There are two cars of \$35 ore from the Black Hawk mine on Murphy hill ready for the smelter.

CLEAR CREEK COUNTY.

(Special Correspondence).—A deal has practically been closed whereby the Virginia City mine is to be transferred to a syndicate of Eastern capitalists for a consideration of \$75,000. The property is owned by Maxwell & Hood, of Georgetown, and has been undergoing development for the last five years. The mine is credited with a production of \$250,000.—The working force at the Josephine mine on Kelso mountain now numbers 50 men. J. R. Sapp, the manager, expects to be sending out from 8 to 10 carloads of galena each month during the balance of the year. The ore is of a high grade and mills from \$60 to \$70 per ton in silver and lead. It is understood that a milling plant is to be installed this fall.—Ore assaying \$93 per ton was cut in the Star property in the Peru district. John O'Dea is manager.—Luzetti & Co., leasing on the Bismark vein, Sherman mountain, has cut a 16-in. streak of high-grade ore in a winze being sunk from the third level.—Shipments are to be started this month at the Culley adit on Saxon mountain. J. J. Culley is manager.—E. J. Butts shipped a carload of smelting ore from the Columbia property last week. The product was sent to the Argo smelter, and settlement was effected at the rate of 2.1 oz. gold and 18 oz. silver per ton.—It is stated that a working fund of \$20,000 has been subscribed for the development of the McKinley mine on Lincoln mountain. On the McKinley vein a streak of lead ore is showing that is from 6 to 10 in. wide and assays \$35 per ton in silver and lead. R. Emery is manager.—Work was resumed this week upon the Merimac group of claims on Kelso mountain. In the shaft workings a streak of \$70 gold-silver-lead ore is exposed that is from 4 to 6 in. wide. As soon as the vein is intersected in the lower workings an increased depth of 200 ft. will be attained.—The Central Colorado mine on Leavenworth mountain is to be developed upon a large scale. C. R. Iliff, of Denver, the owner, states that a company is being organized to drive the adit for 3000 ft. It is now in 350 ft., and for some little distance a streak of \$65 gold and silver bearing ore is exposed that is from 6 to 10 in. wide.

Georgetown, August 23.

GILPIN COUNTY.

The owners of the White Pine mine have leased the Penobscot mill in Gamble gulch and are running a test lot of surface ore through the plant. Ten stamps are running and two concentrators. Work has been resumed in the main Penobscot adit, although the heavy ground makes the progress slow.—A carload of ore was shipped to the Modern smelter near Argo from the Fagrellius mine in Moon gulch for a test run.—The Evergreen mill was shut down for a few days owing to a break in the machinery. A meeting of the stockholders of the Evergreen Gold & Copper Mines Co. was held in Denver recently, and it is reported that an additional force will be placed in the mine to keep the mill working to its full capacity.—Work has been resumed at the Golden Flint mill in Gamble gulch and 15 stamps are kept dropping. A. Bailey is in charge of the work.

GUNNISON COUNTY.

The Blaine Mining Co. at Gothic is repairing the dam which the high water damaged last winter and completing the mill. A cross-cut adit is to be started that will cut the vein at a depth of 500 ft.—Rinehart Holloway has opened a good ore-shoot on his claims in Rustler gulch.—At the Carter property a drift has been started on the vein cut 4700 ft. from the portal of the adit. The vein is 20 ft. wide, all of good ore. The largest portion is a milling grade, with a rich streak of smelting ore.

LAKE COUNTY.

Thomas F. Walsh, of Denver, is to consolidate a number of claims on Corinne mountain. The Corinne group and a number of others in that district have excellent showings and some little surface work has been done, but previously no deep mining attempted.—Harry Schraeder is shipping 200 tons per day from the old Ballard dump to the Leadville District mill.—The Horrigan brothers are to install an electric hoist at the shaft on the Highland Mary and Bobbie Burns claims near Leadville. The ore is still high-grade and is being sacked for shipment to the smelter.

OUBAY COUNTY.

It is understood that the properties of the Mono-Baltic Mining & Smelting Co. near Iron-ton is to be bonded and a smelter erected.—The Ross Mining Co. has commenced grading for the installation of a compressor plant and an electric hoist at the Congress mine near Red mountain. The shaft is now 300 ft. deep and it is the intention of the company to sink 250 ft. farther to the level of the Koehler adit on the San Antonio property and handle the ore that way. Patrick Lonergan is in charge of the work.—At the Legal Tender mine the shaft is down 100 ft. and a hoist is being installed to sink to the 350-ft. level, where cross-cuts will be driven to the contact. Edward Canavan is superintendent.—The raise at the Thistle-down is still in good milling ore.—The Bachelor mine has been unwatered to the second level by Gregory & Co. No attempt will be made to unwater the shaft farther at present, and it is expected the company will commence shipping from this level in a short time.

SUMMIT COUNTY.

There are two electric drills running in the Arctic mine and a large amount of ore is stored on the dump. The mill will be started as soon as the raise is completed to the second level.—The White Cloud Mining Co. has completed the installation of an electric plant in its mill in Summit gulch near Breckenridge and is planning on adding 10 stamps to the mill equipment. L. Simon is manager.—The Sallie Barber mine is shipping a high-grade ore to the zinc smelters.—The Wellington Mines Co. is shipping crude ore and concentrate.—A new crusher has been installed at the Blue Flag mine on Mt. Baldy.—The Gold Bell Mining Co. has purchased the Heter mill and moved it to the Mt. Baldy property.—The Gold Dust mill has been overhauled and is now ready to be operated. There are 500 tons of ore in the mill-bins.

TELLER COUNTY.

There are 30 sets of lessees at work on the property of the El Paso Consolidated company and it is expected the August output will approximate 2000 tons.—The Morris brothers shipped two cars of \$30 ore from their lease on the Morning Star mine on Bull hill.—Grant & McCloud, sub-leasing from the British American Mining Co., opened a 2-ft. vein at a depth of 65 ft. that assays \$280 across the width of the vein.—The Squaw Gulch Leasing Co. has purchased the hoisting plant at the abandoned shaft of the Golden Wedge claim and moved it to the Dolly Varden mine.—Cox & Whetmore have opened a large body of ore on their sub-lease in the Damon mine. A drift has been run 50 ft. on the ore and the vein cross-cut for 40 ft. At present the lessees are breaking 30 tons per day.—J. M. Wright, manager for the Joe Dandy Mining Co., announced that the Jo Dandy and Eclipse No. 1 claims of that company are to be leased shortly.—An ore-shoot that assays \$20 per ton has been cut in the T. E. M. O. M. J. mine by Gus Kelstrom and associates, who are now shipping the ore to the Cripple Creek plants.—Shipping ore has been

opened on the 700-ft. level of the Mollie Kathleen mine on Tenderfoot hill. The cross-cut is also being driven to cut a galena vein on that level.—The Nellie K. Gold Mining & Milling Co. has been incorporated to develop 50 acres on Galena hill north of Gillette.—On the property of the Granite Gold Mining Co., under lease to Furst and associates of Victor, a vein has been opened on the 900-ft. level that assays \$2000 per ton.—The Doctor Jack Pot Mining Co. will pay a dividend of $\frac{1}{2}$ c. per share September 1.

IDAHO.

BONNER COUNTY.

Arrangements are being made by J. Herbert Anderson to re-organize the Panhandle Smelting & Refining Co. and resume operations at Ponderay within 60 days. Present plans call for doubling the capacity of the smelter plant and the building of a branch from the Spokane International railway to the works. It is reported that the Montana Mine Owners' Association has withdrawn from the directorate by the resignation of Albert Wonderlich, of St. Paul, W. L. Hewlett, W. A. Clark, W. G. Conrad, and A. E. Spriggs, of Montana.

IDAHO COUNTY.

The Penn-Dixie Gold Mining Co. has commenced grading for a 4-stamp mill and cyanide plant at its mine near Elk City. No. 3 drift is driven 150 ft. in a 4-ft. vein and a winze sunk from the face 40 ft. in the same ore. No. 2 adit is driven 300 ft. to cross-cut the vein and opened 8 ft. of ore, while No. 3 adit has cut 22 in. of high-grade ore. W. L. Sendker is superintendent.—The No. 1 adit at the Buster mine cut a new shoot of ore under the rich croppings on the top of the hill. J. F. Thorn is superintendent.—The Majestic mine is to be re-opened shortly.—The Larson, Perry, and Brown properties on Rett creek have been bonded and development work is to be started. The dike covered by these claims is 600 ft. wide and has been opened by a 400-ft. drift.—The main adit at the Golden Crown property opened 5 ft. of ore that assays \$6 per ton.

KOOTENAI COUNTY.

The Princess Panama Mining & Smelting Co. at Lake Pend O'Reille have blocked a large amount of ore and are preparing to make a shipment to the Tacoma smelter. The vein has been opened for 4500 ft., with sulphide nearly all the way. James W. Ferguson is manager.

OWYHEE COUNTY.

An average of six samples taken by William Caldwell from the Potosi mine was \$178 gold and 69 oz. silver per ton.—The adit at the mill level of the Banner mine has opened several stringers of ore.

SHOSHONE COUNTY.

At the Star mine near Mullan, 4 ft. of galena ore was opened by the east drift when in 1000 ft. The property adjoins the Morning mine.—On the Carney group a 90-ft. drift has been run in chalcopryite ore.—The ore in the face of the drift recently started on a small seam in the Reindeer mine has widened to 4 ft. of copper ore.—The drift on the 500-ft. level of the Caledonia mine is in 30 ft. on the vein. A portion of the ore is free milling and a portion of shipping grade.—A drift has been driven 500 ft. on the vein at Idaho Northern group near Murray, giving 175 ft. of backs.—The mill at the Monarch mine east of Murray is being enlarged to crush 200 tons per day. The raise is up 430 ft. from the lowest level and the ore opened assays 65% lead and 12 oz. silver. E. P. Spaulding is manager.—The adit at the Blue Bell property on Big creek has been driven 400 ft. to cut the vein and 300 ft. along it. The vein at the point of intersection was 2 ft. wide, but has now increased to 6 ft. Gus Nelson is manager.—Assays on the ore from the veins opened on the property of the Transcontinental Silver & Copper Mining Co., near Mullan, ran from 1 to 7% lead, with several ounces of silver. One of the veins has been opened for 300 ft. along its length and a cross-cut driven across it for over 80 ft.—A contract has been let to drive the lower adit of the Cedar Creek Mining Co. an additional 500 ft. The adit is now in 170 ft., and when the cross-cut opens the vein the rest of the distance called for by the contract will be driven along

the vein. The property is situated east of Murray in Granite gulch.—About 200 tons of lead ore per month are being shipped to the smelter at Salida from the Bear Top mine. The mill has been overhauled and is saving 45 tons of zinc concentrate per month, which the company will ship to Denver or Cleveland. George Kiebler is manager.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Old Judge mine and mill at Oronogo was sold for \$50,000.—The Oronogo Mining Co. has repaired its No. 2 plant and increased its milling capacity to 800 tons per shift. Four other plants are running on the property, with a capacity of 200 tons per day each.—The General Lead & Zinc Co. has started its recently enlarged plant. The mill has a capacity of 150 tons per day and is handling ore from the 190-ft. level.—The Old Dominion Co. has just completed a 350-ton mill for the Puritan Mining Co. in Gordon Hollow, where a number of companies are trying to open the lower formation, which assays from 7 to 8% zinc.—The Columbus Mining Co. has let a contract to build a 150-ton plant near the old Bumblebee property.—The Little Persimon Co. at Carthage is completing a 150-ton mill and will be operating in a short time.—Among the most important recent discoveries is that of A. F. Dexter at Carl Junction, where 90 ft. of ore has been opened by the third drill-hole. The Providence shaft of Webb City is being sunk 20 ft. deeper in a sheet formation that assays 4% zinc. A number of companies in this neighborhood are taking up old stopes and getting good returns.—The Little Pearl Mining Co. west of Joplin has just sunk a shaft through an excellent orebody, 4 ft. of which is almost solid ore, the rest averaging 15% zinc.

Joplin, August 21.

MONTANA.

CHOUTEAU COUNTY.

Operations have ceased at the property of the St. Joe Quartz Mining Co., 30 miles above Avery. Several large loads of mining machinery were on the way to the mine when the order came to shut down. John D. Rockefeller is one of the principal stockholders.

MISSOULA COUNTY.

The Bryan mine at Saltese is to commence shipping to the smelter shortly. The ore is of the lead-silver type with a small gold-copper content.—Stockholders of the Rex Mining Co., operating at Minemile, will meet at Augusta, Maine, September 11, to consider a proposal submitted for a 20 years' lease on the group. The lessees would have to spend \$50,000 in development in opening the mine before beginning to mill and ship.—At the Dennemore property near Saltese the cross-cut adit opened 8 ft. of copper ore. The company expects to sink on this shortly.—A 19-drill compressor and hoisting plant has been installed at the Iron Mountain property near Superior, and a contract let to sink the shaft an additional 150 ft. This property has been a heavy shipper in the past and it is expected to resume shipping in the near future.

NEVADA.

ESMERALDA COUNTY.

At the Florence mill four new Card tables have been set in position and a tube-mill is being installed. This added equipment will raise the capacity of the mill to 160 tons per day. When the addition is completed the ore will be drawn from the Little Florence shaft, and the main Florence shaft enlarged to three compartments.—B. E. Thomas, operating a lease on a claim of the Columbia Mountain Mining Co. on Columbia mountain, opened a rich streak of ore at the bottom of a 125-ft. shaft.—All of the Wingfield properties outside of the Combination ground have been opened to lessees.—On the Poleverde claim of the Jumbo Extension property the 300-ft. shaft is to be deepened to 1000 ft. and cross-cuts run in an attempt to find the continuation of the orebody opened by the Clermont shaft.—The Victor shaft of the C. O. D. Consolidated is to be sunk from the 450 to the 550-ft. level. The sump at the last level opened a vein of quartz but as yet no prospecting has been done upon it, and it is the intention of the management to

open this at the lower level.—A heavier hoisting plant is to be installed on the Garrison lease on Atlanta ground and the shaft sunk to the 550-ft. level. At the 450-ft. level a cross-cut opened a vein which was not of shipping grade, but it is hoped by the management that it will prove profitable on the lower level. The lease is controlled by W. P. Garrison, of Pasadena.—A cross-cut from the 150-ft. level of the Knickerbocker lease on the Blue Bull opened the vein. On the 100-ft. level this vein assayed from \$30 to \$50 per ton, and it is hoped that it will prove of the same value at the lower level.—E. A. Wheeler, S. Canman, and I. H. Cook, of Goldfield, have purchased the Murray 10-stamp mill, the Victor lease, and a portion of the Proskey No. 1 lease at Rawhide. On the Victor ore has been opened from the 135 to the 150-ft. level and four stopes are being worked. On a four days test run on 160 tons of Victor ore a \$4000 gold bar resulted.

EUREKA COUNTY.

Patrick Clark, Dan P. Bagnell, and associates, of Spokane, have organized the Hidden Treasure Mining Co. to take over a group of claims in the Cortez range. An oxidized ore assaying \$25 per ton was cut on the surface, and at a depth of 80 ft. \$80 sulphide ore was opened. The nearest station on the Southern Pacific is Beowane.

NYE COUNTY.

(Special Correspondence).—The Thanksgiving has resumed activities after a long period of idleness. The shaft will be sunk to the 550-ft. level.—A 4-in. shoot of \$150 ore has been struck at a depth of 50 ft. in the Ruth lease on Union No. 2 of the Manhattan Dexter.—The Dexter is installing a hoist and pump to operate below the 275-ft. level.—The Buckeye will be re-opened within a few weeks.—The shaft at the Tolyabe is down 160 ft. on a vein assaying from \$1 to \$40 per ton.—Three shifts are at work on Indian camp. A 10-stamp mill, tube-mill, and cyanide plant, with a daily capacity of 60 tons, will be installed. Electrical machinery is being placed in position.—Placer mining continues to attract principal attention. Local miners assert that the main gulch has been proved for seven miles. The deposits vary from 40 to 80 ft., a large portion of the ground being valueless on the upper strata, but rich near bedrock. The lateral gulch is 10 to 14 ft. deep.—On the Happy Day 10,000 cu. yd. of \$10 gravel are said to be developed.—The Goldfield Bald Mountain Consolidated Co. is opening a large body of gravel at Central. The suction dredge recently installed by Sacramento people is said to be operating satisfactorily.

Manhattan, August 23.

(Special Correspondence).—At the Tonopah mine a large body of ore is being developed on the 600-ft. level, east of the Mizpah shaft. It is reported to assay \$70 per ton and has been opened for 150 ft.—The Tonopah Merger Co. has been organized with 1,000,000 shares, par value \$1, to operate the Golden Anchor group. Additional ground will be purchased and the indebtedness of the Golden Anchor liquidated, according to the plans of the promoters.—Work has been resumed on the 765-ft. level of MacNamara. The company is shipping more ore to the smelters than at any time in its history.—Operations at the Belmont have been slightly retarded while the electric hoist and big compressor were being repaired. The company is shipping nearly two tons of cyanide precipitate and 150 tons of concentrate to Selby each month.—The Nevada-Bellehelen, in the Bellehelen district, is shipping and employing 12 men. The Horseshoe lease has opened a body of fair-grade ore on the Harwood.—It is reported that the Scioto Mining & Milling Co. will erect a custom mill.—The Tonopah Mining Co. has advanced the Nevada Copper Co. \$20,000 for development. The Tonopah company holds the majority interests.

Tonopah, August 24.

WHITE PINE COUNTY.

The fourth unit of the concentrator was turned over to the Steptoe Valley Smelting & Mining Co. after a seven-day trial run. This unit raises the capacity of the McGill plant to 6500 tons per day, all of which is coming from the steam-shovels at Copper Flat. Recently the record for production was broken at Copper Flat by the shipment of 140 cars per

day. This rate will only be continued till the bins at the smelter are filled, when the production will be lowered to 120 cars per day.—Three of the Giroux drills have been moved to the Butte Ely ground, upon which the Giroux company has an option.

OREGON.

BAKER COUNTY.

At the Amazon property in the Greenhorn district a drift has been driven 200 ft. on the vein which is 30 ft. wide. When completed this drift will give 290 ft. of backs on the vein, which is largely free-milling ore. W. F. Prier is superintendent.—Two carloads of machinery for the Cougar mine arrived in Sumpter and is being forwarded to the mine.—The All Metals Recovery Co. of Denver is building a reduction plant on the middle fork of John Day river to treat the output of Ornament, Surprise, and Tiger properties on Greenhorn mountain.

GRANT COUNTY.

The Kennerly Gold Mining Co. is sinking the Ophir shaft to the 200-ft. level. The company is stoping on the first level and has 10 stamps dropping in the mill. The concentrate is hauled in wagons to Austin and shipped to the smelter at Tacoma.

UTAH.

JUAB COUNTY.

Thomas Griffith and Charles Smith shipped a carload of lead-silver ore from their lease on the Utah Consolidated property to the Tintic smelter, the returns on which approximated \$1500.—The Tintic Standard shaft has been timbered to the 400-ft. level and a station cut at that point. New pumps have been installed and the shaft started for the 600-ft. point.—The Tintic Smelting Co. has blown in its fourth unit and the management has sent letters to its customers stating that it was in a position to again accept custom ores.—The property of the Swansea Consolidated Mining Co. at Eureka has been unwatered and a contract let to deepen the shaft 200 ft. This work will sink the shaft to the 1200-ft. level, and here cross-cuts will be run to explore the orebodies on that level.

IRON COUNTY.

The work of installing the new \$50,000 power plant at the Gold Springs mine is to be done by the F. C. Richmond Machinery Co. and will be completed by December 1.

MILLARD COUNTY.

The Antelope Mining Co. in the Blackrock district has opened an 18-in. vein of lead carbonate by a cross-cut adit. The adit is being driven to tap the bottom of the shaft sunk on a vein of copper. The shaft will be continued at that point and a cross-cut driven to the second vein at the lower level.

SALT LAKE COUNTY.

The smelter of the Yampa Smelting Co. at Yampa was seriously damaged by a cloudburst last week. The force of the water threw the ore-bins over, and the water striking the matte caused an explosion that destroyed the reverberatory furnace. The office and store-room of the company were completely destroyed. The tracks have been cleared and one of the blast-furnaces started and the company will continue with a curtailed output until the rest of the plant can be put in running order. The damage is estimated at \$75,000.—The South Columbus Mining Co. has levied an assessment of 5c. per share to raise money for further development work. The company has cut several bodies of carbonate ore, but freight rates are too high to admit of profitable shipping.—The Utah Copper Co. has enlarged its Copperton plant to increase its capacity to 1000 tons of ore per day.—A delay in the completion of the Ohio Copper Co.'s mill has been caused by the contracting firm failing to deliver the structural steel on time. This will delay the opening of the mill until some time in October.

SUMMIT COUNTY.

The Silver King Consolidated Mining Co. has entered suit against the Silver King Coalition Mines Co. in Park City to recover \$5,500,000 as damages for ore claimed to have been removed by the latter company from the Vesu-

vius and Andes claims which the companies own in partnership.

TOOELE COUNTY.

The Western Utah Copper Co. is installing a new compressor and will start work on the 500-ft. level as soon as this work is completed. Good copper-gold-silver ore has been opened on the 300 and 400-ft. levels.

UTAH COUNTY.

The Sierra Mining Co. has been organized at Provo to operate a group of claims which the company has bonded at American Fork.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The lessee of the Quilp mine has shipped two carloads of ore, about 90 tons, to the Granby smelter and has two more ready to ship.—The property of the Lorraine Copper Mining Co. in Keller is in the hands of a receiver and advertised for sale.—A meeting of the Illinois Mining Co. took place in Keller, August 17, when plans were formulated for more extensive development of the company's property.

Republic, August 23.

KITTITAS COUNTY.

A rich discovery has been made on the Jordan and York claim, 1½ miles north of Meaghersville. One piece of ore, 18 in. long, contained about \$300 worth of gold.

OKANOGAN COUNTY.

(Special Correspondence).—The shaft on the Forty-ninth Parallel mine, near Oroville, is down 100 ft. Some rich copper ore has been opened.—The Milwaukee Gold Sands Mining Co. has put a force of men at work on its placer claims, on the Similkameen river, two miles west of Oroville.—The Oroville Consolidated Mining Co. held its annual stockholders' meeting at Oroville, August 7, and elected E. Maccommon president. The company will sink the main shaft on the Sunset group to a depth of 400 ft. and on the 300-ft. level a cross-cut will be driven westward about 400 ft. to tap the Sunset vein. Some rich ore is being mined from a 6½-ft. vein of copper ore. Capital is being raised in New York for development.—The vein of the Rich Bar mine is 8 ft. wide, of which 4 ft. is good payable ore. Fresh capital is being raised for development.

Oroville, August 24.

CANADA.

BRITISH COLUMBIA.

The foundations for the compressor plant for the Greenwood-Phoenix tunnel have been laid and the machinery will be installed as soon as the cement hardens.—The Black Jack claim in the Central camp has been bonded by the Canadian Consolidated Mining Company.

ONTARIO.

A compressor plant is to be installed on the property of the John Black Mining Co. in Cobalt.—On the Imperial Crown a subsidiary company of the Crown Reserve, a 4-in. vein of calcite with cobalt bloom and smaltite has been stripped for 100 ft.—On the Silver Alliance at Elk lake an 8-in. vein of good ore was opened at a depth of 25 feet.

MEXICO.

JALISCO.

Luis Chevrillon has purchased the Mina Grande in the Hostotipaquillo district for English and French interests from the Dwight Furness Cp. The price is said to be \$75,000. The Mina Grande has been worked as a 'glory hole' in the past, and is credited with a large production. The new company will open the property through deep adits. W. A. Hoeing will have charge of the operations.—Frank W. Page, manager for the Lawson Development Co., is authority for the statement that the company's new plant in the Mascota district would be ready to accept custom ore. The mill is now running on ore from the San Jorge mine.—The Lupita Mines Co. in the Mascota district has resumed development work and is to install hoisting and power drilling machinery shortly. Patrick Fitzgerald is manager.—There is \$50,000 worth of ore on the dump at the San José de las Agujas mine near Vavidad that the owners expect to ship to the Lawson Development plant shortly.

Special Correspondence.

LONDON.

Botallack, Cornwall —Mount Morgan Report. — New Taxes in Great Britain.

Several times during the last year or more reference has been made in these letters to the Botallack tin mines in Cornwall which have been re-opened by the Allen & Meyerstein group. These mines are of historic and sentimental interest. They have produced largely in years gone by, and they possess a glamor, owing to their situation on the rocky cliffs near Lands End. It is now two years since the company was formed for the purpose of re-opening them, and though some £60,000 have been spent on development and machinery the mine is not yet in a position to yield regular supplies of ore. This fact is not a reflection on the managers or engineers, but it points out clearly the old axiom that it is more difficult to re-open an old mine than to open a new one. No records were ever kept at Botallack, in which it resembles all the old Cornish mines. The workings had been left in a poor condition, and in some places it looks as if the former owners had abandoned certain parts of the mine on account of collapses rather than from exhaustion of ore. The amount of work required in clearing the shafts and levels, and in combating the water that flowed in from unknown and unexpected sources, has been extensive. A 20-stamp mill and dressing tables have been in operation for over a year, and have treated ore from the dumps, and low-grade ore that had to be cleared out of the levels. It is only quite recently that really payable ore has been found, some in the old stopes and some in new ground, though its extent is as yet unproved. The engineers recommend that the new Allen shaft shall be sunk to greater depth in order that this promising ground may be exploited. As the company has come to the end of its financial resources, income bonds and debentures are being created. At the present time £10,000 is being asked for, but it is evident from the company's reports that quite £50,000 will be eventually required. The company has already mortgaged its property to the Cornish Consolidated Tin Mines, Ltd., the parent company of the Allen-Meyerstein group, as security for advances of working capital, and it is not quite clear how the new issue of debentures and income bonds will stand in connection with this mortgage. It must be confessed that the expectations of the promoters have been realized, the proof of this being the presence at the mine of another 20 stamps delivered some time ago, but not yet erected owing to the absence of ore to treat.

The report of the Mount Morgan Gold Mining Co., of Rockhampton, Queensland, for the year ended May 31 last shows results which are better than might have been expected. It will be remembered that during last autumn a number of accidents occurred owing to the creeping of the ground. It was found necessary to modify the methods of mining, and in the meantime the supplies sent to the mill were interfered with. There are three different sets of plant. One is the battery for treating the oxidized ore; the second is the chlorination plant which deals with pyrite, and the third is the smelter which treats the copper pyrite. The first-named source is becoming exhausted, and will be closed in the near future. During the year in question, 108,191 tons of oxidized ore yielded 17,236 fine ounces, and the contents have dropped to 3.19 dwt., as compared with 12½ dwt. in 1903. Of sulphide ore 106,952 tons yielded 48,284 oz. gold and 453 tons of copper. The ore treated in the smelter amounted to 183,568 tons and yielded 5346 tons of copper and 72,822 oz. gold. These figures are not substantially different from those of a year ago, but if it had not been for the accident the extended accommodation recently provided would have handled a greater output. It is interesting to note that the blister copper will before long be treated at the new electrolytic refinery at Port Kembla, New South Wales. The profits for the year amounted to £228,215, out of which £200,000 has been distributed as dividend.

In a recent issue some information was given relating to

the proposed tax on ungotten minerals in Great Britain. The proposition was to impose a tax of one halfpenny per pound every year on the estimated value of the known coal deposits and ore reserves in metalliferous mines. It is not necessary now to go over the arguments for and against such a tax, as this has been done in previous letters. It is only necessary to announce that the Government has abandoned the proposition, and intends instead to introduce a new tax on royalties.

NEW YORK.

Purloining Collateral.—Sutter Creek Company.—New Mining Stocks.—Temiskaming Difficulties—Greene-Cananea.

The district attorney's office is investigating mining stock frauds which may lead to extraordinary disclosures affecting prominent brokers on the New York Mining Curb market. Recently F. A. Heinze was asked if he could use \$50,000. As he has been severely punished in recent years by the so-called 'Standard Oil crowd', and is involved in many legal tangles, he felt that he had plenty of use for such a sum. What collateral could he put up, was next asked. Plenty of good active mining stocks, Heinze replied, and he named some of them. Finally a loan of \$50,000 for six months at 6% was arranged, and stock of the Davis-Daly and Ohio Copper Mining companies, both of which are controlled by Heinze, was placed with the Windsor Trust Co. as collateral. The day the collateral was placed with the Trust company, a man named Donald Persch informed a Curb broker named John Sherwood that he had a loan of \$50,000 with the Windsor Trust Co., and that he would like Sherwood to take it up so as to release the Ohio and Davis-Daly stocks, placed as collateral. Sherwood was authorized to sell the stock, and to pay the difference between the selling price and the loan to Persch. Sherwood, acting on these instructions, sold a large amount of the stock, and took Persch's order, and the sum of \$50,000, to the Trust company's office. The company willingly returned the whole of the securities to Sherwood on receiving the \$50,000. A couple of days later, Heinze's broker, on purchasing a lot of Ohio Copper shares to protect the market price, discovered some of the shares that had been pledged with the Trust company. He informed Heinze, and the latter communicated with the district attorney. Traps were set, and the whole scheme was uncovered. This is not the first time Heinze's stock has been similarly treated. The district attorney's assistants have found that several times this year similar transactions were carried out on similar lines through the Carnegie Trust company. Curb brokers state that such transactions have been quite common on the Curb recently, and that the gang involved has obtained sums of money from mining stock owners running into several figures. A number of arrests have been made in connection with the frauds and others are pending. The Heinze stock losses will fall chiefly upon the Trust companies. The losses of other stock owners, in many instances, will have to be borne by the owners. The disclosures at present relate only to the theft of mining stocks in New York. There is good reason to believe, however, that later developments will show that similar frauds have been carried out in Boston and in other cities.

A syndicate has incorporated, under the laws of Arizona, a mining corporation with a capital of \$5,000,000, and shares of a par value of \$1 each, to operate a gold mine at Sutter Creek, Amador county, California.

The stock of the Tenabo Mining & Smelting Co., and the Boston & Goldenville Mining Co., have been listed on the New York and Boston Curb markets. The former company was incorporated under the laws of Nevada last year with a capital of \$3,000,000. The company owns a group of copper claims in Wyoming. Development operations have, to date, disclosed upward of \$500,000 worth of ore. The Boston & Goldenville mine is situated at Goldenville, Nova Scotia. It is owned by a Boston company which proposes to make the stock active on the Curb markets. For several weeks past Cobalt stocks have been heavy on the New York Curb market, notwithstanding favorable reports of developments in some of the larger mines. It now

appears that investors are not desirous of dealing in Cobalt stock until the affairs of the Temiskaming and one or two other companies, about which unfavorable reports are circulating, are straightened out. Stockholders of the Temiskaming, which was active in curb-trading early in the year, accuse the directors of market rigging, and call upon them to issue a complete statement as to the company's financial affairs. At the beginning of the year, when attention was given on the exchanges to Cobalt stocks, the Temiskaming directors declared a 6% dividend. They were severely criticised for this, as the published statements of the company did not indicate that it was in a position to make such a disbursement. On June 12 the Directors met and decided that the company was not in a position to declare another dividend. Important brokerage houses in Toronto and New York have sent circulars to the stockholders of the company urging them to demand the Directors to call a meeting to disclose the company's financial position. The company was registered under the laws of Ontario, which provide that upon a requisition by shareholders representing one-tenth of the total number of shares outstanding, the Directors shall call a special general meeting of shareholders to consider such subjects as are mentioned in the requisition. This will undoubtedly be done, and as some of the charges to be made against the Directors are of a sensational nature, much public interest will be awakened. In the meantime Cobalt stocks remain dull and inactive.

In the last 13 months the Greene-Cananea company produced 45,405,000 lb. copper, 1,027,745 oz. silver, and 6616 oz. gold, at its mines in Sonora, Mexico. The returns for July were 3,508,000 lb. copper, 69,975 oz. silver, and 438 oz. gold. The company is now producing copper at a little below 10c. per pound. The directors are discussing plans for the reduction of the company's capital below the present figure of \$7,000,000.

TORONTO, CANADA.

Stock Market.—South Lorrain.—New Silver Field.

The stock market has been characterized by unusual activity for the middle of August. There has been no general or decided advance in prices, but one stock after another has experienced a boom usually following the report of a fresh discovery, which has stimulated speculation mainly among professional traders. This has been generally followed by a recession to about the former figures, but in some cases the advance has been unprecedentedly brisk. Beaver has had two or three spasmodic upward movements lately on the strength of reported new discoveries of rich ore, but the public is disposed to scepticism, as the Beaver veins have an awkward trick of faulting, and boomsters have a way of announcing the picking up of an old vein in a new place as a fresh find.

Mining is going on actively in the South Lorrain district, where about 2500 men are at work. Shipments have begun, the Keeley and the Wettlaufer shipping two cars each. Among the mines in this camp having well equipped plants are the Montrose Cobalt, the Murray, the Magna Cobalt, and the Harris Lorrain. The Silver Eagle has ordered a plant. These mines are controlled by syndicates, and have so far placed no stock on the market. A new silver field has been discovered in the township of Otter, 25 miles north of Thessalon, in the district of Algoma, where two prospectors made the first find last fall, keeping it quiet until they had secured their locations this spring. The news having become public a rush has set in, many having gone from Cobalt and Gowganda. Calcite veins in the diabase have been found as wide as two feet on the surface, and in some cases native silver has been discovered. The prospectors are asking the Government to open a recording office for claims at Thessalon. A large number of members of the British Association for the Advancement of Science, who have come over to attend the annual meeting at Winnipeg, are taking a side trip to the mining regions of northern Ontario in charge of Willet G. Miller, Ontario Provincial Geologist. They were at Cobalt on August 18, where they inspected the leading mining

properties, and after a short stay left for points farther north.

DENVER, COLORADO.

Trans-Mississippi Congress and the Forest Service. — Mining Congress Plans.—Topeka Mine.—Rout County.—Mexican Cement.

Attention in Denver this week has been centered on the Trans-Mississippi Commercial Congress, which has been in session at the auditorium. There was a large and representative attendance, but no lively debates until the last two days when topics relating to the Forest Service and the Public Lands were up for discussion. The Colorado delegation was naturally the largest, and in certain particulars dominated the Congress. Colorado has been restive under the recent administration of the Forest Service and the Land Office, and there was a disposition to indulge in sharp criticism. Under the leadership of ex-Senators T. M. Patterson and Henry Teller, resolutions were introduced designed to rebuke what is called here 'Pinchotism'. F. C. Goudy championed the Governments cause, and proved an able fighter, since he won from an evidently hostile audience, a compromise resolution which takes out all of the sting. The incident is worth noting, since it shows that even here where criticism of the Forest Service is most bitter and wide-spread, it has more friends than enemies. The general sentiment is that the Congress is no longer a fighting organization, and that to some extent, at least, it has become so broad as to obscure its peculiar field of usefulness.

The official call for the Goldfield meeting of the American Mining Congress, September 27 to October 2, has been issued by J. F. Callbreath, Jr., the secretary. It seems likely that discussion will centre mainly on means for stimulating the use of silver, the proposed tonnage tax for meeting the damages due to explosions in coal mines, the projected Federal Bureau of Mines, and the Governmental land policy. Since W. B. Heyburn, Senator from Idaho, and a well-known critic of the Forest Service, is to speak, a lively discussion is anticipated. Among others who have agreed to take part are, E. B. Kirby, S. A. Taylor, H. H. Lang, James H. Fox, H. S. Joseph, D. B. Rushmore, W. C. Ralston, G. O. Smith, Douglas White, Clay Tallman, Chas. J. Moore, L. O. Ray, and Victor C. Alderson. J. J. Hill and R. A. Ballinger will prepare papers, though they may not be able to be present in person. Mr. Callbreath is now in California making preparations for the meeting.

The Topeka mine on Quartz Hill in Gilpin county, has become the sole property of Henry P. Lowe by purchase of the half interest heretofore held by Tyson Dines. The mine was one of the first discovered in this district, and has a long record as a producer. The vein is 4 to 16 ft. wide in parts of the mine, and much rich ore has been extracted. It has been idle for nine years, owing to litigation, but is now being unwatered. The shaft is to be sunk and connection made with the Newhouse tunnel. The breast of the latter is now well in the producing portion of Gilpin county and long-deferred connections are about to be made. The tunnel is already paying interest on its bonds, and it seems that the stockholders are about to be rewarded for their years of waiting.

Rout county has recently come to the front, in the newspapers, and high-grade gold ore was said to have been sent out. A wild stampede resulted. The reports prove to have been fraudulent, but, as often happens, it seems likely that good will come of the rush, since a number of good properties have been located, and some \$100 ore actually shipped. Colorado and Kansas capital are interested in a portland cement plant which is shortly to be erected near Juarez, Mexico. A tract of land on which there are large deposits of limestone and shale has been purchased. The material has been thoroughly tested and arrangements are being made to erect a 2400-bbl. plant. As this will be only the second plant in Mexico, a country which uses 1,500,000 bbl. of cement yearly, the prospects of success are good. W. A. Haggott, of Idaho Springs, has been active in the enterprise, and has associated with himself experienced American cement-makers.

JOHANNESBURG, TRANSVAAL.

Mine Air.—A New Explosive. — Industrial Activity. — Mineral Production.—Transvaal Iron. — Rand Collieries' Development Methods

The Mining Regulations of the Transvaal stipulate that the inflow of fresh air into a mine shall be not less than 70 cu. ft. per man per minute. Like many other Government regulations of excellent purport, it means but little. So long as a mine's atmosphere is not notoriously impure, no unreasonable interference by the officials is experienced. The economic advantages of good air have always been the most important factor in prompting the improvement of ventilation. Although there has lately been upon the Rand, a good deal of 'playing to the gallery' in this matter, and much pretentious advertisement of ventilation schemes which many a coal-miner probably learnt upon his father's knee, there is no doubt good scope for progress and improvement. The problem of ventilation is being attacked from two points of view. First, the engineer concerns himself with the provision of free air to remove the danger of gases, and second, the chemist sets himself the task of minimizing the production of noxious impurities. The manager of the Modderfontein dynamite factory, W. Cullen, and his assistants, now claim to have made a great advance in the right direction by inventing a 'modified explosive' (there are reasons for the lack of closer description), which is as powerful and as cheap as blasting gelatine, but which gives off no CO. Mr. Cullen is too thorough in his methods to make public announcement to this effect, as he now has done, without being satisfied with the finality of his results, the outcome of three years of experimenting. Ordinary blasting gelatine is used almost exclusively in development, and largely in stopes. This, Mr. Cullen asserts, produces CO in 'incredible' quantities, while his new compound (in which, however, it is naturally impossible to introduce sufficient potential oxygen to oxidize the products of the time-fuse combustion), yields it in 'negligible quantities'.

The great wave of activity which developed into a mining and financial boom of some magnitude in June has been checked. Apart from the fact that the buying of shares in worthless undertakings, and the pegging of claims regardless of mining possibilities, were carried to an extreme, the principal course of the present reaction is probably the gloomier aspect of the native labor position. There is a heavy 'wastage' of three or four thousand Kafirs per month, while the requirements of the industry are rapidly expanding. If the shrinkage is soon checked, the temporary shortage will appear more beneficial than otherwise, and will remind the mine-controllers that there is danger in reckoning without their host. The statistics of mineral production in the Transvaal for June show that there has been a small decrease for the half year as compared with the latter half of 1908. The returns are as follows:

| | |
|---------------------------------------|-------------|
| Gold | £15,472,409 |
| Diamonds | 580,807 |
| Coal | 437,555 |
| Base metals | 191,436 |
| Silver contained in gold bullion..... | 41,578 |

£16,723,785

The total for the six months to December 31, 1908, was £16,830,275. Gold and diamonds show a decrease, coal and base metals (notably tin), a fair increase. The Government Mining Engineer has issued a brief report upon the iron ore resources of the Transvaal. With regard to the known deposits, namely, the titaniferous magnetite in the Pretoria district, and at Magnet Heights, the hematite near Middelburg, the ferruginous quartzite and ilmenite near Pretoria, and the 'inexhaustible' bodies of chrome iron ore, the report adds little to public knowledge, but it is of significance in its revelation of the Government's probable attitude toward the future industry. The memorandum recommends the provision of bounties of 15s. per ton, diminishing by 1s. 6d. annually, and also the guarantee of 5% interest on the pioneer company's capital for five years.

A monopoly should be ensured for the venture which first enters the field under approved conditions.

The directors of the Rand Collieries, Ltd., a deep-level gold mine in the East Rand, have determined to adopt a scheme of development which has long been considered economically advisable under certain conditions obtaining on the Rand. Instead of following the 'reef' as hitherto, they will drift in straight lines "in order to traverse the blocks of ground with minimum footage, and therefore cheaper development costs, and also with a view to facilitating tramming operations at a later date." There will certainly be cheaper development costs, but this will be offset by the poorer, that is to say, less informative, developments results. Cross-cuts will be run at intervals of 40 ft. "Therefore", it is announced, "no value can be assigned to the blocks opened up in this manner except at the points at which the cross-cut raises expose the reef." It is when the cross-cut raises fail to cut the reef as expected that the trouble begins. One would like to know a good deal about the character of 'reef-conditions' before deciding upon these straight drifts for mechanical haulage, for in a highly faulted property, (as the Rand Collieries is admitted to be), and where much has to be learnt concerning the average gold-content and percentage of pay-ore, there is a good deal to be said in favor of the old-fashioned method of clinging to the vein, and of regaining it as soon as possible when faulting throws it from the normal course.

ROSSLAND, BRITISH COLUMBIA.

Change of Management at le Roi No. 2. — Silver King. — Dominion Copper Affairs.—Work at B. C. Copper.

There has been a change in the management of the Le Roi 2, Ltd., Paul S. Couldrey, who has been in charge of the property for over six years having resigned to take an office with the B. C. Copper Co. Under the régime of Mr. Couldrey the Le Roi 2, Ltd. has paid steady dividends of nearly \$2 per share per annum. Ernest Levy, who is well acquainted with the conditions here will succeed Mr. Couldrey. It is not likely that there will be any radical change in the policy of the company.

Mining operations at the Silver King mine, at Nelson, will be crippled for some time, as a fire has destroyed nearly all of the surface buildings and has damaged the tramway. The Athabasca mine has been secured by a syndicate of Nelson men who have begun to unwater the mine. Things are still in an uncertain state in Dominion Copper affairs. While amalgamation with the B. C. Copper seems imminent, John Seward has arrived on the ground from New York to take charge. Mr. Seward will first make a thorough examination of the company's property and decide what will be the best policy to pursue. One certain thing is that the management will have to put forth its best efforts to place the property on a profitable footing, especially if it be the intention to do its own smelting. There is a good deal to do in the way of development in the mines if what has already been given out be true, and there is room for great improvement in the ore-handling facilities at the mines, while the smelter as it stands at present presents a problem in itself. It is understood, however, that the General Development Co., of New York, is backing this venture strongly, and there is no doubt that with a good sum of money intelligently and judiciously expended the Dominion property can be made to pay as well as any of the other low-grade Boundary mines. Business is gradually getting under way at the B. C. Copper property. Last week two of the furnaces were started.

The Jackpot mine, recently acquired by this concern in Wellington camp, is showing up in such a satisfactory manner that the adjoining property, the Oxley, has been acquired at a price of \$5000. The Canadian Consolidated has, in the course of its expansive policy, taken a bond on the Black Jack claim in Central camp. Seven carloads of ore were shipped from the Bruce mine, near Midway, last week. The Bruce is proving excellent.

There is a probability of the Jumbo gold mine in the Rossland district being re-opened again. A large quantity of rich ore has been taken out for the amount of development

that has been done. On the Enterprise claim, Norway mountain, a good discovery of free-milling gold ore has been made. A small shipment of sacked ore is being made to the Trail smelter. At the Fife mines a good body of copper ore has been opened in the 'glory-hole', that will assay from \$13 to \$30 per ton. Several carloads will be shipped soon, as the road to the siding has been finished. The shipments from the Centre Star group and the Le Roi No. 2, Ltd., are up to the average. The shaft on the Le Roi No. 2, Ltd., has been sunk to 140 ft. below the 900-ft. level and is still going downward. The ore shipments from the North Star mine in the Nelson district have been climbing for the last several weeks. The Ottawa mine also appears on the list, with a shipment of silver ore. The Second Chance and the Juno claims at Erie have been leased by a local syndicate. Work on the Highland-Buckeye group, near Ainsworth, has reached a point where shipments are about to begin. There is a lot of crude ore now on hand that will assay 60 to 70% lead and 25 to 30 oz. silver. The shipments will be made to the Trail smelter. The Highland mine in 1903 was the largest shipper in this district, the St. Eugene surpassing its output the year following. Since the mine was re-opened several weeks ago a new rich orebody has been uncovered. The coal miners of the Crows Nest coal mining region, or part of them, are forming a Canadian Mine Workers' Union, feeling dissatisfied with the manner in which the local officers of the American union handled the last two strikes; in fact, precipitating the strikes in some cases contrary to vote.

BUTTE, MONTANA.

Electric Power.—Influence on Costs. — Clark Properties. — Davis-Daly.—Tuolumne.—Ohio Keating.—British Butte Dredge.

The introduction of electric power at the Butte mines, to replace steam power, will reduce the cost of production about one-third of a cent per pound, and it will reduce Amalgamated costs considerably below 10c. per pound. A still greater saving will be made at some of the Amalgamated mines when the new Belmont shaft is completed. The Belmont shaft is nearly two miles south of the shafts of the Anaconda, Neveweat, and St. Lawrence mines of the Anaconda company. At present fuel and supplies have to be hauled up hill several miles by steam, and then all the ore must be hauled down again after it has been trammed underground for a mile or two to the hill shafts. A new shaft is also being sunk at the Gagnon mine, an Amalgamated property, and that will serve to make a large saving in operating expenses.

The North Butte, in six months, will have two working shafts in place of one. The North Butte is turning out copper at 8c. or less per pound. Some of the Amalgamated mines are producing copper at 9c., but at several the cost is as high as 13c. The Anaconda group runs between 9 and 10c. Butte Coalition copper, it is estimated, costs about 9½c. The latter company has been under extraordinary expense in development work ever since its organization, in spite of which the cost of production has been gradually reduced. Among the high-cost producers are the Pittsburgh & Montana and the Original Mining Co., the latter owned by W. A. Clark. The public is not much interested in the Clark mines, as they have few stockholders outside of the Clark family. However, it was stated sometime ago, that during the panic the Clark mines were operated at a considerable loss and that it cost 13c. per pound to produce copper from the ores of the Stewart and Original mines. Reports from the Davis-Daly mine are that a big producing property is being opened. In the face of this, however, some of the insiders in Butte, and employees of the company, have been selling the stock lately, a fact that has discouraged outsiders from investing.

The Tuolumne Mining Co., which has a number of stockholders in the East, and also in California, appears to have made a genuine strike on the 1400-ft. level of the Tuolumne mine. The vein, which is believed to be an extension of the Edith May of the North Butte Co., is about 20 ft. wide in the cross-cut, and 11 ft. of it is high grade, assays going as high as 20 to 35% copper. The rest of the vein yields

good concentrating ore. Driving has been started on the vein both east and west. The top of this orebody seems to have been cut on the 1000-ft. level, and is therefore believed to be continuous from that level down below the 1400. The plant, equipped with a Nordberg engine, has a capacity to work to a depth of 3000 ft. The boiler plant of 900 hp. was also installed recently. The shaft has three compartments.

The Ohio-Keating Gold Mining Co., in which a number of New York and Boston capitalists are interested, has made a considerable strike in its property in the Radersburg district, at a depth of 125 ft., where a drift has been extended along the vein. A big body of ore is being developed, and numerous assays show nothing less than \$12 per ton, and many are as high as \$78. Another body of ore was cut in the bottom of the sump of the shaft, 4 ft. wide, and yielding a general average assay of \$51 per ton. The claims of the company are on a vein parallel to the famous old Keating, which produced millions of dollars years ago. It is estimated that within 90 days the property will produce 90 tons of ore per day, netting at least \$20, or \$1000 per day. The company is a Montana corporation, capitalized for 500,000 shares, having a par value of \$1 per share. R. M. Calkins, traffic manager of the Chicago, Milwaukee & Puget Sound railway, is president of the company. The property is equipped with a gasoline hoist, a compressor, machine-drills, and pump, all driven with gasoline power.

The British Butte Mining Co., operating a gold dredge four miles west of Butte, has begun making regular weekly shipments of gold bullion. Last week's clean-up was 93 oz., which netted the company \$1313. It is estimated that this week's clean-up will be at least 50% more. The company has an operating expense of about \$600 per week. The capitalization is \$5,000,000. British Butte owns more than a thousand acres of placer ground. Bedrock is supposed to be nearly 2000 ft. below the surface, as demonstrated by a deep shaft and borings from the bottom. The placer is supposed to cover an old lake bed that drained the surrounding country for ages. There is a false bedrock only a few feet below the surface, and the dredge is working to that depth.

BISBEE, ARIZONA.

Mineral Production.—Tax Rate.—Copper Queen.—Drainage Troubles.—C. & A.—Irish May Shaft.—Precipitation Tank.

The Territorial Auditor, Mr. Foster, has completed the report of the 1908 bullion production of the larger mines in Arizona. The mines reporting are 51 in number, with a total output valued at \$42,249,281. In the previous year 79 mines reported an output above \$5000 each, totaling \$54,788,564. This drop of \$12,500,000 is mainly due to the decline in the value of copper, which had fallen off to little more than half the extreme price reached the previous year. This is shown by the fact that its copper production of the greater mines was larger, having been 291,584,080 lb. compared with 252,784,700 for the year 1907. The silver product reported was 257,697 oz.; gold, 136,059 oz.; lead, 2,995,183 lb., and zinc, 2,457,099 lb. The silver product from practically the same list of mines for 1907 was 2,423,723 oz., and of gold 118,373 oz. The largest gold production came from the United Verde copper mine, at Jerome, being 20,334 oz. Other large producers were the King of Arizona, 11,319 oz.; Congress, 8865; Tom Reed, 8512; Copper Queen, 8352; and Calumet & Arizona, 7628 oz. Copper mines were in the lead also in silver production. The Copper Queen reports 530,490 oz.; United Verde, 494,574; Commonwealth, 416,941; Tombstone Con., 299,597; Superior & Pittsburgh, 182,773; Calumet & Arizona, 155,802; Imperial, 96,614. The Tombstone Con. was the leader in lead, with 1,721,974 lb., together with 231,031 lb. of zinc. The largest zinc product came from the Union Basin Co.'s mines in Mohave county, being 631,588 lb. These reports were gathered and compiled for the purpose of establishing the tax-rate for each mining company on a basis of 25% of the value of the bullion product, this 25% being taken as the value for taxation. Mines producing less than \$5000 per year are taxed under the general law.

Both the Copper Queen and the Calumet & Arizona properties will evidently produce more copper this month than in July, but the Copper Queen will not produce at the same rate as during last winter and spring. This company has been greatly impeded by water, at one time the capacity of the pumps at the Czar shaft being taxed to the utmost, both the steam and electric pumps working at maximum capacity. The old steam pumps were not removed when the electric equipment was installed, and they have proved a most necessary auxiliary under the recent emergencies. Exploration is progressing actively in the lower level, but no important discoveries have been made of late. Driving in the Lowell shaft is now going on at the 1400-ft. level and the connection with the Sacramento will be made in the 1300-ft. winze shortly. At Courtland this company is installing, in union with the Great Western, a community-power house, and development is progressing rapidly. Favorable results have attended the development on the 1400-ft. level of the Superior & Pittsburg, in the sulphide zone. The production from this property will re-

Map of Arizona.

main on practically the same level as in July. In the Hoatson shaft of the C. & A., a body of oxide ore has been developed on the 1300-ft. level, and it is considered of importance because it is the farthest south that any ore has been proved in this district. New machinery is on the ground at the Irish Mag shaft. This includes a new electric hoist and 5000 ft. of cable, and accessory equipment. The shaft will be retimbered at once. Hoisting with the improved shaft and new installation will begin about September 1.

The new precipitating plant at the Copper Queen which is being erected to replace the one which collapsed some three weeks ago, is now nearing completion. The three weeks loss of the copper impregnated water has amounted to a neat sum, but the work of reconstruction has gone forward without delay. The precipitating plant receives the copper-impregnated waters from the mine which are caused to flow over old tin cans and scrap-iron. In the rainy season the saving by this method is a not unimportant matter. The old plant collapsed by reason of the copper sulphate solution eating the nails with which the structure was joined. In the new plant this has been avoided by using wooden pegs in place of nails.

Work on the Bernoudy-Turkey Creek property is being pushed actively, and on September 1 a large force of miners will be added.

MEXICO.

Alvarado Consolidated Mines Co.—San Francisco del Oro.—Cuadras Mine.—El Carmen, Inde, Durango.—Manta Mining Co.—Promoter Arrested.

The spirit of the clause No. 44 in last year's draft for a mining law, which was withdrawn, has cropped up in a new way. Formerly when concessions were granted, the possessive clause read: "that the concession was granted to the individual named or to the company which he might organize." It is to be noted that nearly all of the concessions now granted, and published in the *Diario Oficial* have the possessive clause worded: "*para por si ó por medio de la compañía Mexicana que al efecto organice, conforme á las leyes de la República,*" etc., which translated means that the concession is granted for the individual use of the concessionaire or the Mexican company which may be organized for the purpose, in accord with the laws of the Republic. There is also a clause which expressly stipulates that the concession cannot be passed to a foreign corporation for any motive whatsoever. A letter was recently sent by the Secretary of the Treasury, José Yves Limantour, to the Board of Directors of the National Railroads, requesting that natives be given the preference in promotion and employment whenever possible, and also criticizing the Board for not having Mexicanized the great body of railroad employees more rapidly. This letter has been the subject of much comment. A great many foreigners have taken it as indicating a willingness on the part of the Government to pander to the anti-foreign agitation which exists in certain sections. A meeting of protest was organized in the American colony in Mexico City to see what could be done to prevent the publication of so much exaggeration and misstatement by the United States daily press about Mexican affairs. In Chihuahua a current of quiet negotiation runs throughout the State, but matters were particularly awakened by the long-time lease on the Palmillo, of Pedro Alvarado, in Parral. Even this, however, was rather hawked around for a considerable period, not because it lacked value, but more because of its magnitude, until finally the present holders, A. J. McQuatters and James I. Long, obtained control. They first took it over on a leasehold, organized a \$5,000,000 company, and started unwatering. This gave them plenty of opportunity to thoroughly examine the property, and it was not long before they made a deal with Alvarado for the purchase of the property at \$1,000,000. The company was at once re-organized under the name of the Alvarado Consolidated Mines Co., with a \$10,000,000 capital. Of this a goodly portion has been sold to obtain working capital, and for the erection of a 1000-ton mill. The milling company will be in a sense separate, as the Palmillo Milling Co., of \$1,000,000 capital, is a subsidiary of the mining company, and the mill will be erected, as production demands, in units of 250 tons each. It will be of the fine-concentration type, followed by cyanidation, and will do a custom business as well. It is stated that there are 300,000 tons of \$10 ore blocked in the upper levels of the mine, and that there are 200,000 tons of a similar grade on the dumps; that this ore can be treated at \$3 per ton, leaving a profit of \$7 per ton, or a total of \$3,500,000, more than three times the cost of the mine. This looks well, but there does not seem to have been taken into account the cost of mining, which certainly could not have been included in the \$3, for in a camp where all kinds of supplies are high, where labor is no longer cheap, and at a mine where they will be required to pump continually from 1200 to 1500 gal. per minute from a considerable depth, the cost of mining is no small item. That the Palmillo is a good mine and will pay well, there is no doubt, but the enormous capitalization of the new company gives it rather a bad flavor. With the resuscitation of the Palmillo comes also that of the San Francisco del Oro, lying between Parral and Santa Barbara, not only by a practical re-organization of the old company (in the form of a rather stiff assessment), but a change of management. This property has what is undoubtedly one of the largest deposits of complex sulphides in Mexico, and under the management of J. E. Hyslop, the English company spent several hundred thousand pounds with no re-

turns, experimenting with simple concentration, oil separation, the Sutton-Steele, and others, without success, until the company's money was exhausted. A thorough re-examination of the mine was made, and the mine was reported upon favorably; additional funds were raised, but a new management was called for, and the property has now been placed in the hands of William S. Harrison. As yet little is being done, but a careful study is being made of the problem, and it is thought that success may crown this new effort. Adjoining the San Francisco del Oro, the Cuadras mine, owned by the Marina Mines of Mexico, Ltd., and held under lease and bond for £20,000 by Charles M. Hobson, has been taken over by the Torreón Metallurgical Co., and 25 tons per day are being shipped to the latter's plant at Torreón.

Frank Husted, of Parral, has organized a new company, with American capital, to take all the properties held by him and Messrs. Iwansky and Hemminghoffen at Indé, Durango, and some gold properties held by Mr. Husted in the El Carmen district. New and larger shafts will be put in where needed; air-drills will be introduced at El Carmen; and a cyanide plant will be erected for the ores from the Santa Lucía, Santa Eduwigs, and the Campana. The shipping ores have been contracted for with the American Smelting & Refining Co. At the new concentrating mill of the American Zinc Extraction Co., at Parral, three Huntington mills have been added for finer grinding.

J. E. Hyslop, former manager for the San Francisco del Oro, with Walter MacLachlin, a director of the said company, and Mr. Holms, formerly with the Palmarejo and

Palmillo, Parral.

Mexican Gold Fields, Ltd., have organized in London the Manta Mining Co., with £100,000 capital, for taking over 19½ pertenencias in the Santa Eulalia district, near Chihuahua, known as the Carmen-Negrita group, and situated near the rich Mina Vieja of the American Smelting & Refining Co. Mr. Hyslop and associates are said to have £25,000 working capital, and work has already been started. It is believed that good returns may soon be expected from this new enterprise. Some work had already been done on the Carmen, and it was known to have good ore, though no large body has been proved.

Pedro Noriega Ruiz, promoter of the Gallega and Cuatro Señores mines, against whom an accusation of fraud was pending, was arrested day before yesterday in Vera Cruz, and has been consigned to Belén to await trial. Noriega, it is alleged, promoted a company to develop the two mines which are situated at Zacualpán in the State of Mexico, and sold shares to the extent of more than \$30,000 to mining brokers in Mexico City. It is claimed that he collected the value of the shares from his purchasers, giving in return receipts, and promising to deliver the certificates of stock as soon as his title to the properties should be perfected by the Department of Fomento. It is said that Noriega left in August of 1907, and has never been heard of since. Upon his disappearance, a group of his creditors, headed by Juan Roustand and Lic. Eusebio E. Miranda, notified the Department of Fomento of the matter, asking that the deeds to the properties be not delivered to Noriega. At the same time a formal accusation was made against the promoter, and the matter was put in the hands of the police. Hearing from its agents in Vera Cruz that Noriega had been seen in that city, the chief of the secret service, Francisco Chávez, ordered his arrest. Noriega disclaims fraudulent intentions or acts. He denied having received money from Roustand, and said that he could prove that all his transaction in Mexico have been upright.

SALT LAKE, UTAH.

Cole-Ryan After Lead Mines.—Ray Con. & Gila Will Produce Heavily.—United States Copper Furnaces.

Repeated efforts have been made to form a merger of mining properties in Park City. At first the Bamberger interests attempted to get the Ontario, Daly, and Daly-West properties to unite. It was also intended to take in the Little Bell, Thompson, and several adjoining properties in which the Bamberger syndicate had an interest. The Eastern interests in the Daly-West balked at this, and for a time an effort was made to get the control of that mine from the Bambergers. Recently a successful termination of the efforts at a coalition of the West Quincy and Thompson properties has been brought about, and in the meantime the controlling interests in Daly-Judge are continuing their warfare on the Bamberger interests and hope to be able to wrest the control from them at the next annual meeting of the shareholders. An effort has been made to get the Silver King Coalition Mines Co., the only regular dividend-payer of Park City, into this consolidation. By getting the Silver King in the deal it was hoped to also include the Daly-Judge, so that one company might have all the producing ground in that great silver-lead district which has produced more than \$100,000,000 worth of ore and has paid half this amount in dividends to its shareholders. As the Silver King was much more valuable than all of the other properties, and as its owners could see no advantage in a consolidation, the scheme failed. Recently the Cole-Ryan people have been endeavoring to get control of the silver-lead product for their new smelting plant in Pine canyon. They have held conferences with the owners of these properties, and while nothing has been arrived at, it is learned that they hope to corral these producers and thereby get control of the output of the principal silver and lead properties in Utah. As a first step in this direction they have made overtures to F. Augustus Heinze for his 10-year contract for smelting the Silver King ores. They have not come to terms as yet because the Silver King will not agree to a transfer unless the terms of the smelting contract are modified. This has decided the Cole-Ryan agents to continue the original effort for buying the properties outright, and this move is being watched with much interest, as such a purchase would involve many millions of dollars.

Daniel C. Jackling says that Ray Consolidated and the Gila copper properties will be in position to begin regular production of ore within one year. The new milling plant, having a capacity of 5000 to 6000 tons per day, will be completed by that time, and the Ray now has 50,000,000 tons of 2½% copper ore proved. The Gila is developing at a rapid rate, and its ores will be treated by the mill on the Ray property. Actual construction will begin on September 15, while the steel material will begin to arrive on September 1. The Gila will have about half as much mineral territory as the Ray. There is a community of interest in these properties, and they will be worked almost on the same plan.

George W. Heintz, general manager for the United States Smelting, Refining & Mining Co., says that they have a great deal of the work completed on the new copper furnaces. They are taking some of the material from the old Bingham Consolidated smelter, which was closed by order of the Court on January 1907. Both the Bingham and Utah Consolidated plants are being dismantled, the International Smelting Co. taking the equipment and some of the material from the Utah smelter. The bag-house will be the last portion of the copper plant to be completed for the United States company. It is expected to have some of the copper furnaces running not later than next January, and from that date the company will be in the market for copper ores. With the Garfield, United States, and International Smelting plants in the field for copper ores, the competition promises to be keen and to make this one of the greatest smelting points in the world. The three plants will have a combined daily capacity of 8000 tons of ore.

The Crowther leasing company at Park City is shipping \$15,000 worth of ore per month to the smelters. The company has also erected a small mill making four tons of concentrate per diem.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Flashing point is the term applied to the particular temperature for any volatile combustible substance at which it gives off an ignitable vapor.

Impact pulverizers have an important application in certain classes of crushing for concentration, especially where the ore contains much pyrite. The Sturtevant, Williams, Raymond, and Cyclone are all impact machines.

Mundic is a Cornish term applied to pyrites, either ordinary iron pyrite or marcasite. When arsenopyrite is present it is called arsenical mundic. The term is used considerably in Canada, but not to any great extent in the United States.

Diamond-drill holes invariably depart from a straight line, and need to be surveyed, special apparatus being purchasable for that purpose. Contrary to what might be expected, horizontal holes deviate less from a right line than those inclined toward the vertical.

Hot-blast yields no important advantage in pyrite smelting, and the efforts to utilize it have been abandoned, together with the attempt to smelt pyritically, without coke. At present so-called pyritic smelting is effected with the use of from 1 to 3% of coke.

Juvenile waters are those which issue from deep-seated magmas, and hence constitute a new addition to the waters on the surface of the earth. They are generally highly charged with mineral matter, and are carriers of metals. A large number of veins are formed by the action of juvenile or magmatic waters.

Strength of materials is decreased by fatigue. Constant application of a relatively small stress will produce a rupture in a material having theoretically a resistance exceeding the amount so applied. This is called 'fatigue of material'. Fatigue is more marked if the stress alternate from tension to compression and back again.

Lime in solution is present as the bi-carbonate, $\text{CaH}_2\text{C}_2\text{O}_6$. On the breaking up of the bi-carbonic ion, HCO_3 , carbon dioxide, is given off, and the normal calcium carbonate is formed. As this is insoluble it precipitates. In this manner deposits of calcareous sinter, onyx marble, and cave-marble are produced.

Gold mining costs have probably reached a lower limit at the Alaska Treadwell property on Douglas Island, Alaska, than at any other mine in the world. The total cost of mining and milling is \$1.40 per ton, the average yield from the ore being \$2.18 per ton. The treatment consists of amalgamation and concentration. There are two mills of 240 and 300 stamps, crushing respectively 4.51 and 5.5 tons per stamp.

The cost of milling is about 18c. per ton. The deepest level of the mine is 1450, the bulk of the output coming from the levels between 600 and 1050 feet.

When a force is applied to a piece of material the stress is not instantaneously produced, but moves with a wave-motion through the mass. The velocity of this motion can be found, and it is shown to depend upon the stiffness and density of the material. The velocity of stress should be taken into account in problems involving impact and suddenly applied loads.

Alkali-waste from the ammonia-process for making carbonate of soda contains chiefly lime carbonate in a soft state resulting from precipitation. There is also present some lime hydrate. When the amount of magnesia is low it makes an acceptable material for the manufacture of portland cement. The cement from this material is made by the 'slurry' or wet-process.

Mining claims duly located, and held by performance of all the legal requirements, carry with them absolute control of the surface right, inclusive of the products of the soil; but an owner of a claim, or one holding a claim by performance of assessment work, has no cause for action at law because of destruction of any crops growing thereon, due to stray cattle, unless the claim be properly fenced.

Arsenic and antimony are associated with most silver ores, and occur down to great depths at Kongsberg, Norway, at Guanajuato, Mexico, and elsewhere. There seems to be no limit in depth for the formation of arsenical and antimonial minerals so far as exploration has yet gone, but in a general way it may be said that the richer deposits have been discovered at no great depth below the present surface.

Eight men locate and stake a valid association placer claim in March 1896; in April 1906, seven of the original locators quit-claim to the eighth, who duly files deed for record; in February 1907, one of the original locators dies; during this year \$100 worth of work is performed; during 1908 \$600 worth of work is done, and the deputy mineral surveyor runs out the lines of the original location and shows this claim to overlap adjacent patented ground. There being unlimited vacant ground suitable for the purpose, and it being imperative to command the entire 160 acres for drainage purposes, the question arises, how can one individual (the deed-holder) amend or re-locate so as to exclude the overlap and include an equal amount of new ground in a manner acceptable to the land-office, being a 160-acre claim. Excepting only the locator who died, the deed-holder is in touch with all the original locators, and if that would cure it he could quit-claim back to them all, except the one who has died. The law does not require that the 160 acres shall constitute one square quarter of a section; the grouping of the eight claims in one association claim may be according to the desires of the locators. The legal difficulty might be overcome by introducing an eighth party in a re-location and obtain the requisite quit-claims.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Russian Money Trust.

The Editor:

Sir—I am astonished that such an article as the one headed 'A Russian Money Trust', should have found its way into the columns of your issue of August 7. Such a mass of nonsense and falsehood is seldom found in two and a half columns of printed matter, and its facts and conclusions sound much like those of some of the rabid free-silver orators of Mr. Bryan's first campaign. It is evident that Mr. Walsh, whoever he may be, is entirely ignorant of the mining of platinum in the Ural region; and having certain theories about money-trusts and governments, manufactures his facts *ad libitum* to support his contentions. It seems to be his desire to prove that the Russian Government has manipulated a platinum 'corner' after the approved methods of the operators in the Chicago wheat-pit, and that by backing a "small coterie of mine owners," by coining and withdrawing from coinage, and other schemes, has fixed the price at will to suit its own purposes. What utter rot! The platinum industry is of great interest to the whole world in view of the numerous uses to which the metal is now put, and the false impressions created by such an article as the one in question, certainly ought to be corrected by a statement of the facts.

An examination of the first paragraph fails to disclose a single statement that is not false. "A small coterie of mine owners, backed by the Russian Government, has enjoyed for years one of the closest monopolies of the world." Does not this sound like populistic twaddle? The fact is, the land in the platinum-producing regions has been classed in two categories, that held in large landed estates, and Government land, open to mineral location. The former was granted in large tracts at an early date in connection with the opening up of the country, and more especially for the development of the Ural iron industry, which Russia found so necessary for ordnance in the seventeenth century. The latter has nearly all been taken up in mining claims under the liberal Russian mining law. In neither does the Government concern itself today further than to encourage the mineral production and collect the small tax levied on the output. In this connection Mr. Walsh would be interested to read the proceedings of the conventions of the Association of Gold and Platinum Miners of Russia.

Platinum in the Urals always occurs in connection with gold in the placers, and in the earlier days was of course regarded as a drawback. Early in the nineteenth century Government ownership and operation of gold mines in the Ural region was discontinued, and private enterprise was given a chance. With this came an increasing production of platinum, a metal for which at that time there was little mar-

ket. Intrinsically there was no reason why it should not be used the same as gold, and Russia, rather at a disadvantage with other European countries in respect to metallic currency, was easily persuaded in 1826 to begin the coinage of a limited amount of platinum. This was continued at intervals until 1864. The reason why this did not prove successful, and why the Government ceased coining platinum, does not require the ingenious explanation given in Mr. Walsh's fourth paragraph. It is perfectly evident to anyone who has studied the subject of money. The fact was that it was impossible to keep in circulation a metal the value of which was continually fluctuating and with a ratio to gold that was always changing.

Then Mr. Walsh goes on to tell of the Government's attempt to recall the platinum money and how this was found to be impossible because the peasants had hoarded it. More absurdities! The platinum coins never had a wide circulation, and the only effort the Government ever made to recall them was to offer to redeem them when their coinage was discontinued. Some were offered for redemption, but a large proportion was preserved as curiosities, and even before the recent remarkable rise in the value of platinum, they were held at a good premium. I remember in the early nineties seeing them brought out in country homes and displayed as rarities. "Over a half million dollars' worth of the coins is hidden away, and only occasionally small quantities leak out and find their way to the Government Mint." I venture to say that the amount of platinum coins owned by collectors is very much more than this, and when any of them are melted up it is not by the mint, but by the jewelers. The introduction of platinum diamond-settings and other platinum jewelry by Fabergé, the famous jeweler of St. Petersburg, was a noteworthy achievement.

To return now to the first paragraph. The Russians are notoriously lacking in industrial enterprise, and practically throughout the nineteenth century the platinum industry underwent little or no change. The right to locate mining claims was gradually extended to include a larger number of people, and the discovery and opening up of new placers went on slowly. Of all the Ural gold region, the rivers richest in their proportion of platinum were the Iss and the Tura, and as the demand for platinum began to increase, more attention began to be paid to this field. There is no such place in the Ural as the "mining settlement of Miac," which Mr. Walsh mentions; it is possible that he has thus incorrectly translated 'Miass', the centre of a large gold mining region, far removed, however, from the platinum district. It was not the Russian Government, but French capitalists who first saw the industrial opportunities offered by the platinum placers, in view of the rise in price, and the limited supply. A syndicate was quietly formed in Paris, of French capitalists, and as many as possible of the mining claims along the two rivers above mentioned were purchased. It was not long before the public awoke to the fact that the platinum market was cornered, and the price was gradually raised to more than that of gold.

The worst of it is that there has never been a time

since the formation of the French syndicate that it has not been possible to obtain plenty of platinum-bearing ground in the Urals outside of what they own. Americans, who are usually enterprising in seeking new mining fields, especially where clever methods of working will mean increased profits, have neglected this region and have allowed the French to keep their monopoly. For a number of years the large private estates in the Urals were in the market, but American mining men paid no attention to them. Later the French company contracted for the whole output of most of these estates at a price that averaged about \$13 per ounce, in order to forestall competition. Even at the present time there are many good properties to be had; not for nothing, however, but at a fair price; and these would yield an excellent return with good management and improved methods. Some of the lower reaches of the platinum-bearing streams are being worked by means of small dredges. The present practice in this work is crude, and here is offered a fine opportunity for American enterprise. Several of the large land-owners of the Ural have untouched platinum ground that sooner or later can be purchased, and those who have already contracted their product for a period of years, will soon be in the market again. Russian geologists have recorded several instances of finding platinum in the rock, but thus far no body of platinum-bearing ore has been discovered. It is quite possible that such a body may be found some day, and then the shares of the French platinum trust will take a bad drop.

In conclusion, let me quote two sentences from Mr. Walsh's article. Compare the statements contained in the two. "Many times in the past Russia has used this absolute monopoly to pay her debts, and after the close of her war with Japan she increased the price of platinum to help her recuperate." "The total annual product of the platinum deposits of the Ural Mountains does not exceed in value \$2,000,000." Further comment would appear to be superfluous.

JEROME B. LANDFIELD.

Binghamton, New York, August 12.

Churn-Drill Gravel-Sampling.

The Editor:

Sir—In your issue of March 6 I note an article on 'Churn-Drill Sampling', by W. E. Thorne, and I notice in this article that he confines his attention entirely to the drilling accompanied by driving the casing to bedrock. I wish to call your attention to my experience with a churn-drill method that avoids many pit-falls described by Mr. Thorne. The method that I have used is one that sinks the pipe to bedrock with little or no driving, and as a result I am convinced that it secures more reliable samples. The object of drilling placer-ground is to get a sample which is a cylinder of material of a certain diameter. In either case a pipe is sunk to bedrock, and the material enclosed by the casing is recovered and its actual gold content extracted.

There are two methods of sinking casing used today; one wherein the pipe is driven, and the other where it is sunk by weight, aided by rotation. There are numerous objections to the driving method.

These were well recited by W. E. Thorne in his article, as follows: "The material that belongs to the core is driven aside. The core may be compacted by driving, and if a considerable difference in the water-level between the inside and outside of the pipe occurs, and the core is suddenly loosened, material then runs into the pipe and gives false results. Flat rocks may be encountered, as described in this article, and driven aside. Intermittent pumping with a large pump results in a sudden lowering of the water-level inside the casing, and then the sudden inflow from the outside carries material with it that properly does not belong to the core."

I have used several types of hand-prospecting drills, one of which uses rotation and weight as a means of sinking the pipe. This is known as the 'Empire' method. The casing is constantly rotated by hand or by animal power. It has a sharp-toothed cutting-shoe on the bottom. The platform is attached to the top, and on it three or four men stand, who do the churn-drilling, using a tool which is a drill and pump combined. The weight of the casing, of the platform, of the men who stand on it, and of the drill-rods and tools, aggregates nearly one ton. This weight sinks the casing owing to the fact that it is kept always loose by being rotated. The cutting-shoe penetrates the gravel and cuts a clean core, and as this core works up into the pipe it is further drilled and picked up at once by a drill-pump. This is a regular sand-pump with a ball-valve, having a circular, hollow drilling-bit attached to its lower end. With this combination-pump the core is pumped as fast as it is drilled. It is seldom necessary to drive the casing, and when it must be done a small amount only is needed, for the pipe, always being rotated, is always loose and sinks easily under the weight of men and platform, as above explained.

The disadvantages mentioned by Mr. Thorne are obviated in this method, and a truly representative sample is had. The drill is really a combination core and churn-drill, and its action is to cut a core like a core-drill. This is done by a sharp-toothed cutting-shoe of nickel-steel which is attached to the lower end of the casing. The casing is revolved by horse or man-power, and the cutting-shoe acts like a 'Calyx' drill in cutting and loosening the core.

The pump with its drilling-bit cannot be operated below the casing, owing to the fact that a safety-clamp prevents, therefore many of the difficulties resulting from drilling below the casing in steam-drilling are obviated. If a boulder be encountered and it becomes necessary to drill below the casing, then the tools are changed and a regular rock-drilling bit is substituted for the drilling-pump, and the boulder is drilled through or shattered by the combined action of the drilling and the driving of the casing. In steam-drill practice a vacuum-pump of large capacity is used at intermittent periods and the large volume of water suddenly removed from the inside of the casing causes a great in-rush from the outside, whereas with the 'Empire' method the pumping and removal of the core are continuous.

In steam-drilling a foot or more is drilled at a time with a heavy drilling-bit and the material is drilled so fine that it results in sliming the core and

the mineral content, thus causing consequent losses. With the 'Empire' method the core is drilled and pumped as soon as it enters the casing, and gravel under an inch in diameter is often picked up in the pump without being drilled at all, and the core is not slimed or pulverized by excessive drilling, as so often happens with the steam-drill. With the steam-drill the cutting-shoe has very thick tapering or wedge-shaped walls, as it must stand the force of the large driving-effort, and these thick wedge-shaped walls tend to crowd material inside or outside and cause an inaccurate core. A thin shoe, however, with straight walls, in rotating, instead of driving, cuts a clean core of a constant diameter.

When operating in loose ground, sinking the casing by rotation and pressure or weight prevents the loose ground from running into the pipe. The casing is always loose on being rotated, and immediately sinks through any soft spot that may be encountered, thus maintaining an accurate core. In steam-drilling it may happen that the drill breaks through from hard ground to soft, and drilling proceeds below the casing, in which case the loose outside ground runs into the casing and gives inaccurate results, removing many objections stated by Mr. Thorne.

Mr. Thorne cites several discrepancies between the results of churn-drill prospecting and dredging, and many more can be shown where casing was sunk by driving. An admirable book on 'Dredging for Gold in California', by D'Arcy Weatherbe, cites wide discrepancies between the results of churn-drilling with driven casing, and subsequent dredging-results, some of these running over 200%. It is of more than passing interest to note an instance where ground was drilled with a churn-drill with rotated casing and each clean-up of the dredge compared with the value as shown by the drill-holes dredged out during the previous run. The extremes were as follows: drilling was to dredging as 96.6 is to 100 and as 103 is to 100. When results for a considerable time were averaged, it was found that the drilling and dredging results practically coincided.

Many other discrepancies are encountered in driving casing not mentioned by Mr. Thorne, such as injury to the casing and the difficulty encountered in pulling it. If the casing be rotated during its entire period of sinking, it is always loose and there is no trouble whatever in pulling it. This is an important feature. It often occurs that a string of driven-casing is lost by the joints pulling apart while the casing is being pulled. I maintain that drilling, when carried on with churn-drills, using rotated casing, is more accurate, and its results more reliable than can possibly be had where shafts are sunk in wet ground or below the water-level of a placer. Shaft-sinking in wet ground is costly and often impossible without large pumps, and results obtained under such conditions are absolutely unreliable on account of the material running in from the outside with the flow of water. The conditions that interfere so seriously with shaft-sinking have no ill effect upon drilling with the rotated casing method. It is worth noting that it is not possible to sink shafts in beds of streams without caissons and compressed air. The hand-drill, with rotated casing, works un-

der such conditions with great ease while floated on a small scow or a few canoes.

Slime.

The Editor:

Sir—Following the discussion of slime in the MINING AND SCIENTIFIC PRESS, I would say that all non-crystalline (solid) and non-crystalloid (liquid) matter can be called colloidal. If suspended in a liquid, it is a sol; if coagulated, it is a gel. The latter (which a few writers unfortunately call a pectoid) can be stained by dyes. I have used malachite-green oxalate largely. The action of a dye (color base + acid radical) in staining clay is strictly analogous to that of CaCl_2 ; both may be adsorbed and displaced.

The clay gels have the property of adsorbing or taking up basic atoms from solution. This is usually an exchange. Thus the action of calcium chloride may be illustrated as follows:

The Ca can be recovered from the gel by displacing it with an excess of another salt, namely:

Precious metals in true solution would act like Ca in the equations above.

Fine grinding, by increasing the amount of colloid matter would in that respect tend toward the retention of bi and tri-valent metals; unless these metals are displaced by excess of some cheap soluble salt.

When a solution is in such condition that colloidal matter if present would tend to assume the sol form, the fall of all particles will be retarded. This is when either or both the hydroxyl ion concentration is high and the viscosity is high. But the presence of the colloids is not essential, although they, like soluble salts, may be accessory to such changes in the rate of subsidence.

Asbestine.

The Editor:

Sir—I notice on page 181 of your issue of August 7 that under the heading 'Asbestos', you refer to a product called 'asbestine', used as a pigment. The connection in which this fact is mentioned implies that asbestine is either a variety of asbestos or a product derived from asbestos mines. Such, however, is not the case; what is called asbestine in the trade is not asbestos, but a fibrous variety of talc. The mineralogical name of this talc is agalite, which is a pseudomorph after tremolite. This material is mined, and prepared for the market, at and near Gouverneur, New York, in the Adirondack mountains. There is no asbestos produced, nor has it ever been found there to my knowledge.

GEOLOGY OF NORTHERN MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. BURBOWS.

The mining districts adjacent to the line of the Kansas City, Mexico & Orient railway, taking in a strip about 70 miles in width by 400 in length, extend from Presidio del Norte on the Rio Grande, to Topolobampo on the Gulf of California. The territory in question may be most conveniently subdivided into three regions, namely, the Eastern, Sierra, and Western. These subdivisions may be fairly well defined. They differ from each other essentially in physiographic features, climate, geology, and character of mineral deposits. Beginning at the Gulf of California, the Western region may be considered to extend from the Coast to the western base of the Sierra Madre, a distance of about 150 kilometres (96 miles). Continuing eastward from this line, the Sierra region will be assumed to extend to the line of the Mexican Central railway. From this line, the Eastern region extends to the Rio Grande. The Eastern region, which is especially discussed in this paper, is characterized by an almost even distribution of mountain and plain, the mountains consisting of isolated peaks or ranges of small extent, while in the Sierra the mountains predominate, running in more or less extended ranges, until the continuous chain of the Sierra Madre is reached. The almost level surface of the Western region is interrupted only by the narrow range of hills that crosses the Fuerte river at San Blas, the plain being bounded on the west by the San Blas range that fronts the Gulf of California.

The general geology of the three regions is different. The Eastern region is mainly underlaid by sedimentary rocks. The Sierra province is almost entirely covered by late eruptives. The Western region differs from both in the constitution of its bedrock, which is principally granite, and older than the others. The difference in altitude, and the great difference in the quantity of rainfall in the three regions, gives each a different climate, causing an essentially different flora, with corresponding variety in agricultural conditions. The extensive plains of the Eastern province, with their deep, rich soil, are, through lack of moisture, of little utility except for grazing. On the contrary, through the constancy of the summer rains, and the persistence of the streams in the Sierra and Western regions, crops may be raised wherever sufficient soil can be found to cover the seed.

EASTERN REGION.

The general character of the Eastern region is that of regularly alternating mountain and plain, the latter remarkably level, with an average altitude of 4000 ft. above sea-level. The mountains rise abruptly to additional heights of 500 to 2500 ft. The region is traversed by the river Conchos, which, running at almost right angles to the mountain chains, has cut through some of them near their points of greatest elevation. The eccentric course of this river is a most striking phenomenon, and difficult to account for. Instead of choosing the easier

course through the plains, it has cut through the rocky strata of the ranges, at practically their central points. The proper course for the stream would seem to be a continuation of the San Pedro river near its junction with the Conchos. Following that course it would have passed to the south, avoiding the high ranges, finding an easy path across the north end of the Chilicote plain, and thence through the Puerto del Gato straight to the Rio Grande. Instead of that it goes out of its way to plunge into the heart of the mountains, preferring a tortuous course through a dark rocky enclosure, rather than the straight path through the open freedom of the plain. In passing through the mountain ranges, the river has carved deep canyons, impassable at many points, some of them not far inferior to the barrancas of the Sierra Madre in their abruptness. Entering the region from the southwest, the river turns around the Sierra San Diego, and running northward through the plain, for about 20 miles between two mountain ranges, makes a right angle to cut through the Sierra del Morrión. It then traverses another narrow plain, plunging again into the Sierra de Santo Domingo, from which it emerges into a long valley, in which are some of the most fertile lands of the region. After meandering through this valley the river cuts across the range at Las Vigas to enter the valley of San Pedro, leaving it through the San Pedro range to emerge into the valley of Cuchillo Parado. To escape from this valley, the river breaks directly through the high range of Cuchillo Parado in a series of picturesque canyons, from which it finally debouches into the valley of the Rio Grande. As a source of water supply in its lower reaches, the Conchos river is exceedingly erratic. With its headwaters reaching to the summit, and draining about 400 kilometres (250 miles) along the eastern slope of the Sierra Madre, it is influenced by the summer rains of the Sierra region, becoming a mighty river at times. During the dry season the irrigation ditches take practically all of the water except the underflow, so that it is possible to cross in many places dry shod. It is a great pity that the enormous quantities of water now going to waste in the rainy season cannot be deflected to the plains that lie on either side. These, if watered, would prove one of the great sources of wealth in the Republic.

A good idea of the topography of the Eastern region may be obtained by traveling eastward from the City of Chihuahua over the K. C. M. & O. railway. The manner in which the road winds around the bases of the mountain ranges, passing from one valley to another, demonstrates the interrupted character of the ranges and the way the plains are linked. Few of the ranges exceed 20 miles in length, their axes having a general northwest direction, corresponding to folds and faults that are probably contemporary with the elevation of the central plateau. The breaks in the continuity of the ranges are mostly due to variations in the intensity of the folding, and sometimes to faults, an example of the latter occurring at the break in the Sierra de Aldama, where the Chuvisear river enters the Aldama plain. That part of the range lying north of the river, has been

raised several thousand feet. The most extensive mountain chain is that of Cuchillo Parado, about 70 miles in length, forming in its continuity a notable exception to the other elevated portions of the region. Owing its origin to a great fold, which is traceable northwestward in somewhat interrupted series of ranges almost to El Paso, it determines in a great measure the course of the Rio Grande for a considerable distance, the river following approximately parallel to the axis of the fold.

By reason of the isolated character of the mountains, the plains run together at numerous points, forming continuous stretches of practically level ground. Good wagon roads are the rule, and the entire region is comparatively accessible. Although relatively narrow, some of the plains extend for im-

dise, before the advent of the railroads. It is still the highroad of communication that connects Ojinaga and other settlements of the Rio Grande with the interior of the Republic. As the distance between watering places is often 50 miles, this plain has claimed a number of victims. Heavily laden, slow-traveling wagons go provided with barrels, lashed one on each side, carrying two days' supply for man and beast.

Although the term 'desert' is frequently applied to these plains, conjuring up visions of the sandy Sahara, the only feature that renders them deserving of the epithet is the lack of water, there being no sandy wastes and few rocky barrens. Vegetation is by no means scanty, grass growing thickly all over the plains and mountains, with patches of mes-

La Boquilla, Conchos River, Chihuahua.

mense distances, demonstrating the great uniformity of the earth-movement which gave rise to the peculiar topography. Considered as topographic units, the plains are remarkable. The plain of Aldama, from 20 to 30 kilometres in width, extends from the Sierra de Naica on the south, without interruption northward, passing the international boundary and stretching into Arizona, a distance of about 500 miles. South of the Conchos river, the Chilicote plain, 75 miles wide, extends southward into the neighboring State of Coahuila, a distance of fully 275 miles. Dotted here and there over its surface, small ranges and lone peaks give the effect of an archipelago of rocky islands emerging from the ocean. Across the northern end of this plain lies the old road from Presidio del Norte, which constituted one of the principal thoroughfares between Mexico and the United States for the caravans of merchan-

quite and other brush at intervals. The atmosphere is dry and the rainfall light. Numerous attempts have been made to procure water by digging wells, and although the ground beneath is moist, most attempts have resulted in failure.

The bedrock of the Eastern region is composed mainly of marine sedimentary beds, that have been subjected to extreme folding by a force that seems to have operated uniformly along the entire Gulf slope, the disturbance in this section being the expression of the forces, that raised the Sierra Madre Oriental, and which probably began with the post-Laramie movement that elevated the Rocky Mountain chain. In the region under consideration, the folds formed parallel elevations with intervening valleys, their axes having a general northwest direction. The uplifted ridges constituted barriers, which, retaining the drainage of the region, formed

a parallel system of long narrow lakes, that extended north and south for hundreds of miles, and well back toward the Sierra Madre on the west. These lakes subsisted a sufficient period to allow deposition of immense beds of gravel, attaining a thickness of several hundred feet. Minor earth-movements during the latter period of the existence of the lakes, culminated in opening passages for the water through the mountain barriers, finally draining the lakes and determining the present water-courses.

Small areas of igneous rocks are scattered over the region, increasing in extent as the Sierra is approached; these igneous rocks form outliers of the tuffs and lava that make up the Sierra Madre. The lower sedimentary rocks of the region, that is, the rocks between and including the Boquilla slates and the Aurora limestones, probably extended westward to a shore-line about the centre of the Sierra Madre: the continent at that period stretching away to the west. After the deposition of the Aurora formation, the sea became rapidly shallower, as attested by the large amount of fossil wood and remains of land animals found in the Ojinaga beds. The shore receded nearly to the line now marked by the Rio Grande. Owing to the depth of gravel and silt, the bedrock is concealed to a great extent in the valleys and plains, though well exposed in the mountain ranges, especially along the Conchos river. The formations in these latter localities have been thoroughly dissected, offering good opportunities for their examination, although even at these points the excessive crumpling of the strata frequently obscures the relations of the beds.

The accompanying plan and section, although incomplete, will illustrate to some extent the geological sequence and conditions of the Eastern region. The names given to the formations are arbitrary, the writer's familiarity with the geology of the Mexican border being insufficient to permit the correlation of the formations with recognized horizons. The following detailed description is more for the purpose of setting forth the economic importance of the beds, than of a complete geological discussion. The formations will be regarded in the order of their succession, beginning with those apparently oldest.

BOQUILLA SLATES.

These are probably the oldest sedimentaries exposed in the region, the only locality where they were observed being in the gorge of the Conchos river, just above the Boquilla, near Santo Domingo. In this locality the slates are about 1000 ft. thick, forming the core of the Santo Domingo range, and extending both north and south of the Conchos. Their extent northward was not determined, but they were traced south almost to Coyamito mountain, a distance of 6 miles. The amount of distortion precluded following any well defined strike or dip. Neither could any well marked contact be found between it and the overlying beds, the two rocks being perhaps unconformable. The rock is a clay slate, extremely fissile, and having a tendency to break into small wedge-shaped fragments. Neither organic remains nor any other evidence to indicate the age of the beds could be found, except their in-

ferior position, which, taken together with their probable unconformability, suggests the possibility of a pre-Cretaceous origin.

The only sign of mineralization consists of small veins of quartz, the thickest of which was less than an inch wide, containing no metallic minerals, in spite of the fact that the overlying formations are rich in metallic deposits. It is evident that the texture of the rocks prevented their fissuring to a sufficient extent for the admission of mineral solutions.

PLOMOSAS FORMATION.

Above the Boquilla slates, sloping from the Santo Domingo range eastward toward the plain, may be seen a system of beds consisting mainly of limestones and shales, with a layer of conglomerate near the centre and quartzite at the base, having an aggregate thickness near Plomosas, of about 1150 ft. These beds extend along the eastern base of the Santo Domingo range, showing plainly at some points, and at others disappearing under the alluvium of the plain. Although the outcrop is interrupted south of Plomosas, it is probable that the limestones of the Cerro de Coyamito, south of the Conchos river, belong to these beds. No organic remains were noticed in this formation. Embracing the zinc and lead deposits of Las Plomosas and the copper prospects of Coyamito, this formation is of considerable economic importance, having produced and still yielding large quantities of ore. Referring to the sketch, and beginning at the base of the range where the beds emerge from the plain, there occurs 160 ft. of shale containing three interbedded layers of limestone, the latter with small deposits of lead and zinc, which lie practically parallel to the planes of bedding. The next in succession is a bed of massive limestone 450 ft. thick, in which the large ore-bodies are found, occurring as irregular deposits nearly parallel to the planes of bedding, and also in short fissures striking across the stratification. Under the massive limestone, layers of shale, aggregating 180 ft. in thickness, are followed by 80 ft. of conglomerate, both of the latter, so far as known, being barren of ore. Under the conglomerate comes 200 ft. of limestone, which is remarkable as containing iron and copper ores to the exclusion of lead and zinc.

This is in contradistinction to the upper limestones, which contain lead and zinc, but no copper. At the base of the formation is seen a bed of quartzite 100 ft. thick, much shattered in places, and showing a network of quartz veinlets with an occasional trace of copper. All mining in the vicinity has practically been confined to the exploitation of the lead and zinc ores in the heavy bedded limestones near the centre of the formation, the copper prospects having received much less attention than they really merit, according to their surface-indications. South of the Conchos river, about 18 kilometres from Las Plomosas, the Plomosas formation again appears in the Cerro de Coyamito, where the beds are seen to dip toward the west. Small quantities of lead and zinc are found here, but the principal mineralization seems to consist of bodies of iron gossan containing traces of copper. These deposits occur in the central body of limestones, parallel to their bedding-planes,

and are traceable at least two miles, varying from one foot to a hundred in width.

ORE DEPOSITS OF LAS PLOMOSAS.

Just how long the mines of Las Plomosas have been worked is not of record, but it is likely they have been operated in a desultory way for a hundred years or more. Lead was the sole object of value in these mines in earlier times. The zinc being useless was left in the mine. The high price of zinc during the last few years, drew attention to the district, resulting in the re-opening of the old mines as well as the discovery of numerous orebodies hitherto unknown. The camp being situated within five miles of Pica-chos station, on the Orient railway, with which it is connected by a wagon road, makes it easily acces-sible. The mineral in the shape of smithsonite, has

next to the iron oxide, and extending from both sides toward the centre, were well defined streaks of smithsonite. Exemplifying the last phase of de-position, was a core of lead carbonate occupying the centre of the cavity. The separation between the lead-ore and the zinc was fairly well defined; that between the zinc and iron not quite so well defined, but still enough so to permit mining the ore com-paratively clean. In one of the stopes, the lead ore had been taken out by the old miners, thus leaving the zinc exposed on either wall, so that the present

Section at Las Plomosas.

operators had only to strip off the clean zinc ore. This was an extremely cheap method of mining, and, as one of the miners remarked, it was little short of finding the ore piled up on the roadside.

From the evidences which exist in the neighbor-hood, it is probable that these deposits have been formed from the decomposition of mixed sulphides of lead, zinc, and iron, and the successive re-deposi-tion of these minerals in the shape of oxides and carbonates. Small stringers of mixed galena, blende, and pyrite are found by cross-cutting the limestones, these stringers having retained their normal con-stitution through some condition which has pre-

Eastern Chihuahua, Mexico.

State of Chihuahua, Mexico.

been admitted into the United States free of duty, to which circumstance alone is due the profitable ex-ploitation of the ores. The lead and zinc minerals exist almost separately in the ore-cavities, passing from one mineral to the other so abruptly as to make a fairly clean extraction of the different ores. The extent of purity attained in the mining of the zinc may be understood when it is known that a great deal of the carbonate ore assays 50% Zn in large shipments. The purer ore is generally of a honey-yellow color, and aside from its weight, has at first sight more the appearance of a limestone concretion than that of a metallic mineral, the successive layers of the deposit being clearly distinct, and in some cases so thin that 16 layers to the inch may be counted.

The conditions of mineralization at the Juarez mine exemplify the type of ore deposit in the dis-trict, and merit description for this reason. This mine is on a short fissure of varying width, running obliquely across the limestones. The stopes showed, first, a deposit of calcite and iron oxide on the walls;

vented access of atmospheric water or other decom-posing agency. It is, therefore, likely that these streaks represent the primary mineralization. Ad-ditional evidence may be cited in the occurrence of native sulphur crystallized within the body of the calcite which forms the gangue of the deposits, this sulphur most probably having been derived from the decomposition of the original sulphides.

LAS VIGAS FORMATION.

Between the Plomosas and Las Vigas forma-tions, several hundred feet of rocks occur, which at all points examined were so covered with gravel and soil, that their nature could not be determined. It is prob-able, however, that they are the continuation up-ward of the shales seen at the summit of the Plomo-sas formation. The Las Vigas formation, through

the hardness of the sandstones which constitute its most prominent feature, outcrops as a distinct ridge, traversing the country for miles. It may be seen in the long ridge traceable from Chorreras on the south to Las Trancas on the north, a distance of over ten miles, and at Cuchillo Parado for an even greater distance. The locality of Las Vigas, which has been described by Walter Harvey Weed, is, perhaps, the most familiarly known along the various outcrops of this formation. This fact has promoted the selection of that name to facilitate description. The conditions at Chorreras, however, although practically the same as at Las Vigas, are more familiar to the writer, and will be taken as a basis for description.

At Chorreras, the formation has a thickness of about 2000 ft., and consists of gray calcareous sandstone and shale in alternate beds, the latter rock predominating. Topographically, the formation is characterized by a succession of ridges with intervening hollows, the ridges forming the outcrops of the sandstones, the hollows indicating the position of the shales. The base of the formation as seen at Cuchillo Parado and Chorreras, is represented by a bed of arenaceous limestone, about 250 ft. thick, the next in succession being beds of calcareous sandstone, aggregating a thickness of 700 ft. In these latter are found the principal copper deposits belonging to the formation. Next occurs 240 ft. of black shale, followed by thin sandstones, which alternate with shales to an additional thickness of 750 ft., where it passes into the shales and gypsum of the Cuchillo formation. With the exception of a few obscure remains, resembling plant stems, no fossils were found. In spite of the extreme aridity of the region, this formation yields water plentifully at slight depths, most of the shafts that have been sunk revealing water in abundance. As a rule this water contains iron sulphate and free acid in solution. Water for domestic purposes is derived from springs in the neighboring formations.

The first mining of copper from this formation, so far as known, dates back to the year 1870, at which time the mines of Santa Sofia and Santa Cristina were actively worked, the ore, consisting of oxides and carbonates, being reduced on the spot in adobe furnaces with charcoal as fuel. As the workings penetrated the sulphide zone, operations were suspended, until the establishment of railroads and smelters in the Republic encouraged the re-opening of the old mines. As this involved a wagon haul of 75 miles to the Mexican Central, together with a costly railroad transportation to the smelter at Aguascalientes, this period of activity was short lived, and the mines again became dormant until the commencement of work on the Kansas City, Mexico & Orient railway drew attention to the mineral resources of eastern Chihuahua. About this time the Santa Cristina mine was acquired by the Hathaway Brothers, who began sorting the old dump, shipping the product to Aldama by wagon, and thence by railroad to the smelters, making a profit in a few months of \$10,000, that amount representing the purchase price of the mine.

The orebodies are parallel to the bedding of the formation, occupying and adjacent to narrow fis-

tures, made by the slipping of the sandstones on each other or on the shales. This movement must have been due to the excessive bending of the strata in the vicinity, causing the different beds to slip on each other as sheets of paper are seen to do under similar conditions. Evidences of such movement are conspicuous throughout the formation, although perhaps less so at points where extensive mineralization has caused partial disintegration of the adjacent rocks. The ores are exclusively copper, and consist of narrow streaks of solid mineral filling the cavities between the sandstone and shale. There is also impregnation of the adjacent rocks to some distance from the plane of movement, the workable ore varying from a few inches to 8 ft. in width. The shoots of ore are fairly constant, that of Santa Cris-

Santo Domingo Range.
Showing Fault, Upper Right-Hand Corner.

tina, which extends into the Justicia claim, being little less than a thousand feet in length. The ores at and near the surface, consist of carbonates and copper oxides, the carbonate stains coloring the rocks for a considerable distance from the veins. As permanent water-level is soon reached, the oxidized ores do not persist to any great depth, chalcopryite taking their place. Gray copper was observed at the mine of La Lágrima, three miles north of Santa Cristina, and it is worthy of note that this mineral assayed much higher in silver than either the chalcopryite or the oxidized ores, the gray copper carrying an average of 40 oz. per ton, while the latter seldom contain one-quarter of that amount. The gray copper is evidently a secondary mineral here, as it is seen to pass into chalcopryite near the bottom of the mine, although the lowest working is only 60 ft. below surface.

(To be Continued.)

BOSTON-SUNSHINE MILL.

Written for the MINING AND SCIENTIFIC PRESS
By G. W. WOOD.

In July, 1908, I was employed by the Boston-Sunshine Gold Mining Co. to design plans for re-modeling the old Sunshine mill, at Sunshine, Utah, and I afterward supervised the construction and have operated the mill up to date. The process as used and the method of treating the ore, were substantially the same as those followed in a number of mills in the Black Hills of South Dakota, which are operated by or under the supervision of J. V. N. Dorr, of Denver, Colorado, milling ores amenable to the same treatment, although the Black Hills ores are chiefly silicious, while at Sunshine the ore consists largely of 'talc'; in both of these, however, the treatment is practically identical. The history of the Sunshine mill, with its record of four unsuccessful attempts to treat the ore, is sufficiently well known. These failures were probably due to improperly separating the slime from the sand, and to consequent failure to properly leach the latter; also there was failure to get good extraction from the slime at a reasonable cost.

Prior to re-construction, the mill-building and such of the old machinery as was subsequently used, were in good condition, considering that the property had been idle for several years. In reconstructing this mill, the boiler and engine rooms, crushing room, hoist room, and the mine and crushed-ore bins, were allowed to remain intact, with the exception of a few minor changes and repairs; the lower end of the mill only being reconstructed and adapted to the new process. Hoisting, crushing, and elevating are done by steam-power; from that point electric power is used.

The process used is as follows: Referring to the plans of the re-modeled mill, the ore as it enters is tripped from a skip into the mine ore-bin; from here it drops by gravity over grizzlies, the fine ore going directly to the elevator boot, the over-size going to two gyratory crushers. From the crushers the ore goes through a revolving screen, the fine going directly to the elevator boot, the over-size to rolls and thence to the elevator boot. All of the ore is elevated by an endless belt bucket-elevator and dumped into the crushed-ore bin. From this the ore is fed to an endless belt conveyor by which it is carried up into a mixer-classifier, of a type designed by Geo. H. Dern, general manager for the Consolidated Mercur Gold Mines Co. The slime at the overflow end of this mixer-classifier goes by gravity to a Dorr classifier, the sand from the sand-end going to a second mixer-classifier. The sand from this goes direct to the sand tanks for leaching, the slime to the Dorr classifier, together with the slime from the first mixer-classifier for further classification. From the Dorr classifier the sand goes direct to the sand tanks for leaching, mixed with sand from the second mixer-classifier, and thence to the sand tailing dump. The slime goes to a 12 by 35-ft. settling tank, in which is operated a Dorr continuous slime-thickener. The thickened slime is drawn out at the bottom of this tank through a 4-in. pipe, as desired, by opening

and closing a gate-valve operated from the Moore-process floor, and is forced by difference of head to the charging-vat of the Moore process.

The Moore process, as installed here, consists of three rectangular vats, with hopper bottoms, and two sets of filter-leaves built up in two movable frames, connected to vacuum-pumps; also an additional vat for cleaning the filter-leaves. The operation of the Moore process is as follows: A clean frame is first immersed in the charging-vat. The suction from the pumps then draws the mill-solution from the thickened slime through the leaves. This comes out as 'gold-solution,' and at the same time the pulp builds up a cake on the leaves, requiring from 30 to 45 minutes to make a cake $\frac{7}{8}$ in. thick, dependent upon the thickness of the pulp. After having picked up about a $\frac{7}{8}$ -in. cake, the frame is lifted by means of a hydraulic crane, and is deposited in the barren-solution vat, where clear barren solution is drawn through for further extraction of the metal in the cake already picked up. After a given length of time, dependent upon the assays, the frame is moved from the barren-solution

Boston Sunshine Mill.

vat to the wash-water vat. In this, wash water is drawn through the frame for a sufficient length of time to extract the remaining metal which may be recovered advantageously, and to displace the cyanide solution in the filter-leaves and cake. Water and air are then forced through the leaves in inverse order, the cake drops off, and falling to the bottom of the vat is forced out as slime-tailing, by the head of water above it. This is done by opening a sluice-gate operated from the Moore-process floor. Both frames are operated continuously at the same time, but, of course, each frame being at a different stage of the cycle. The constant-level tanks, operated by means of float-valves, ensure a uniform rate of flow throughout when the valves are opened at given points.

A series of gauge-boards, assembled at the Moore-process floor, with wires connected to floats in the mill-solution storage, mill-solution sump, barren-solution storage, barren-solution sump, and gold-tanks, indicate at all times, at this point, the tons of solution which these tanks respectively contain. An electric gong, also connected with the same, rings when any of the tanks are filled within a given distance from the top. This ensures prompt attention without close watching, and prevents the tanks from overflowing. Sampling is done in this mill auto-

matically. At the elevator head is an ore-sampler making uniform grabs, and operated at regular intervals by means of dumping-buckets, placed over the mill-solution sump, with which it is connected. A sampler over the barren-solution sump, operated by the solution flowing through it, continuously measures the amount of barren solution going into the barren-solution sump, and at the same time takes uniform samples at regular intervals. This sampler also operates another, taking uniform samples of gold-solution flowing into the gold-tanks, simultaneously with the barren-solution sample. The tons of solution registered by the first sampler multiplied by the value of the gold-solution sample, less the value remaining in the barren-solution sample, is the value precipitated. For a period of five months this sampler, in one of the Black Hills mills, has checked up within 0.11 of 1% with the bullion.

In the general arrangement of this mill, in comparison with some others, it may seem crowded, but in this instance it is a distinct advantage. Everything in connection with leaching is in sight, or is at hand, and can be reached from the Moore-process floor at a moment's notice in the event of anything going wrong. A man standing on that floor, on the side toward the sand-tanks, can see the pumps, shafting, and motor in the pump-room below, and the Moore-process pumps and other apparatus on the floor he is on. Above him are in sight the classifiers, launders, conveyor, motor, and shafting; the gauge-boards at his side keep him posted as to the quantity of solution in the various tanks and sumps. A few steps up and he can look directly into the sand and settling-tanks.

The ore, by differences, from actual milling, has consisted of 50.85% sand and 49.15 slime; sand-tailing has averaged about 60c., slime-tailing 20c., the general tailing for the month of May having been 39.3c. The heads during May averaged \$3.48. Two hundred tons of ore have been treated in this mill in 24 hours without appreciable inconvenience. The extraction for the month of May, the second month's run, was 88.7%, at a cost of milling of 84.9c. per ton of ore.

HAND CHURN DRILLING.

Written for the MINING AND SCIENTIFIC PRESS
By O. H. PACKER.

Hand-churn drills are used for testing foundation-soil and rock for large buildings, piers, and the like, and for drilling holes for blasting cuts for railroads and wagon-roads, especially when only a small amount of work is necessary, or when the rock is extremely soft. They are made of ordinary octagonal or hexagonal drill-steel, except that, when holes over 30 ft. deep are required, hollow drill-stems are used. Taper-joints should be used for the connections, because this kind of joint is less liable to become loosened than a common pipe-joint, and is about twice as strong. The threads should be kept clean and protected from injury by thread-protector caps.

The hole is begun with a hand-hammer and short drills called 'starters,' one man turning the drill for one or two strikers. The 'starters' are used till the holes are 6 to 8 ft. deep, though in extremely hard

rock striking may be continued as long as satisfactory progress can be made. In churning, one or two men churn the drill up and down, making strokes about one foot long, and turning it slightly at each blow. Water is poured in as required, and the hole is cleaned out with a sand-pump instead of a 'spoon scraper'. This so-called sand-pump is simply a length of thin casing provided with a valve at the bottom, and attached to a rope for lowering and hoisting. In drilling through gravel, or in any case where the hole has a tendency to cave, clay is dropped into the hole at regular intervals. This plasters the hole and answers the purpose of a casing in a feeble yet satisfactory way. As the hole is deepened, requiring longer, heavier drills, more men are employed, five being the greatest number that can conveniently work on one drill. Even with four men some device for securing detachable arms to the drill-stem is desirable. When the weight of the drill becomes excessive the bit is screwed to hollow stems. By this means holes have been churned over 70 ft. deep. Casing can be used in conjunction with hand-churn drills, the drillers standing upon a platform secured to the casing. The weight of the drillers forces the casing down as it is turned by means of flat-link chain-pipe wrenches.

In testing foundation-soil and rock the composition of the formation may be determined by examining the material brought up by the sand-pump with a good hand magnifying lens. The hardness of the formation can be most satisfactorily determined by the 'feel' of the drill as it strikes the bottom of the hole. In making cuts through hills or ridges for roads, two rows of holes are drilled the entire length of the cut, the distance between the holes being made about equal to their depth. If the rock is quite hard it will be found more satisfactory to make the depth greater than the spacing distance. In any case the holes should be drilled from 2 to 4 ft. deeper than the required grade. If the holes are drilled only 2 ft. below the grade a ridge will be left to be later drilled (by hand-hammer drill) and blasted. It is better to drill 4 ft. below grade, so as to shake up and shatter the rock down to grade. This latter method will result in a saving of money, because the cost of churning 2 ft. deeper will be less than that of drilling and blasting out the ridge between the rows of holes. There are cases, however, where it is not permissible to drill below grade. When this is the case some advantage is had by spacing the holes closer.

The speed of hand-churn drilling is about the same as that with double-hand hammer drills in drift mining in similar rock. The cost of churn-drilling will, therefore, vary from hand-hammer drilling according to the number of men employed to operate the drill. Hand-churn drills may be used for many kinds of work not mentioned above. For example, they may be used to good advantage in making prospect cuts and holes, and for grading for mill-building foundations. For such purposes a 10 or 12-ft. hole will usually be sufficient. This is 'sprung' once or twice, loaded with black powder, and fired. If several holes are to be fired at once use an electric blasting machine, so as to fire all the holes at the same instant.

GASES RESULTING FROM HIGH EXPLOSIVES.

By WM. CULLEN.

*The explosive mostly used on the Rand is blasting gelatine; practically no other is employed in driving, developing, and shaft sinking. My work has been mainly confined to the gases resulting from the use of this explosive, occasionally slightly modified on lines which will be indicated. On being completely detonated, only carbonic acid, vapor of water, and nitrogen are formed—all comparatively innocuous gases. The particular equation which shows this result is confirmed by explosion inside a steel bomb. Incidentally, I may mention that the cartridge wrapper, which Dr. Moir assumed took part in the explosion and led to the production of carbon monoxide, does not do so, at least not to any extent, as I have demonstrated more than once. This, however, is a side issue. My contention has always been that if the conditions of the steel bomb were imitated as nearly as possible in practice, we should get results which at least approximate to the theoretical, that is, if the explosive is carefully tamped and certain other precautions taken. In no case was I able to get results which have the slightest resemblance to the theoretical. All the experiments were conducted in drifts, that is, on development work, and a sample of the mine-gas was generally taken before blasting—at a certain point. Immediately after the blast and before any air was turned on, the sampler proceeded to the same spot, generally 30 to 40 ft. from the face, wearing a safety helmet, and again sampled the gases from the blast. The actual sampling was done as follows: At the point fixed on, the sample bottle was opened, air was introduced into it by means of the bellows, which were emptied and filled 50 times. The same operation was gone through after the explosion. Scores of samples of mine-air have been analyzed, and although in most cases I have been given permission to make use of the figures, I do not propose to avail myself of this privilege to any extent. I may say, however, in passing that most of the samples were very bad indeed, though it is only fair to add, that in many cases those samples were taken from particular parts of the mine which were known to be bad. The astonishing thing about all these analyses is the almost universal presence of carbon monoxide, and more often than not, in dangerous quantity.

There is a general impression that old explosives give much worse results than new; and that is so, as most people know, when we speak of the age of explosives in terms of years. Again, there is a difference of opinion with regard to the best size of detonators, some contending that better results are obtained with No. 8 than with No. 6, and vice versa. With regard to tamping I hold rather extreme views. I have always had the idea that the current practice of employing sand cartridges was wrong in principle on account of the friable nature of the sand. Clay, to my mind, was infinitely preferable, so a comparison was tried. Incidentally, I may mention that Mr. Leslie, of the Simmer & Jack, who holds similar

*Abstract from Jour. Chem. Met. & Mg. Soc. of South Africa.

views to my own, employs clay, and asserts that he gets much better work in practice. Then there was the vexed question of the benefit, or otherwise, of the so-called neutralizers, or anti-fume mixtures, of which there are sundry varieties on the market. There were various minor points, but the most important of all was to ascertain whether better all round results could not be obtained from a blasting gelatine which was so modified as to contain within itself more than the normal amount of oxygen. These experiments are unfortunately not yet concluded, but they have already given some valuable data.

I look upon the analyses of the resultant gases as the most accurate means of measuring the work done. The more completely the explosive is resolved into the simple gaseous mixture of vapor of water, carbonic acid, and nitrogen, the better should be the 'footage', to use a technical term. Certain experiments seem to incline this way, but the results are not conclusive, and the experiments must be continued. No matter how perfect the conditions were, large amounts of carbon monoxide were always formed, and incidentally the conditions under which the experiments were carried out were above the average, in so far as exercise of care is concerned.

In every case when not otherwise specified the tamping used was the ordinary sand cartridge.

TABLE I. RESULTS OBTAINED FROM BLASTING ROUNDS.

| No. of experiment. | Explosive. | Detonator | Distance from face. | Gas Composition. | | Ratio of CO to CO ₂ |
|--------------------|---|-----------|---------------------|------------------|-------------------|--------------------------------|
| | | | | CO % | CO ₂ % | |
| 1a ... | Ordinary blasting gelatine | 6 | 35 ft. | 0.012* | 0.134* | 1—7.8 |
| 1b ... | 3 months old | | | 0.88 | 6.32 | |
| 3a ... | Newly made blasting gelatine | 6 | 27 ft. | 0.026* | 0.328* | |
| 3b ... | Ordinary blasting gelatine | | | 1.09 | 6.56 | 1—6 |
| 4a ... | 3 months old | 8 | 44 ft. | 1.28 | 8.07 | 1—6.3 |
| 4b ... | Blasting gelatine 3 months old with neutralizer | 6 | 35 ft. | 0.021* | 0.290* | 1—8.2 |
| 2a ... | Special composition blasting gelatine | 6 | 40 ft. | 0.013* | 0.50* | |
| 2b ... | Special composition blasting gelatine | 6 | 40 ft. | 0.56 | 3.7 | |
| 5a ... | Special composition blasting gelatine | 6 | 40 ft. | 0.011* | 0.216* | 1—6.6 |
| 5b ... | Modification of 2 | 8 | 16 ft. | 0.007* | 0.123* | 1—7.9 |
| 12a ... | Modification of 5 | 8 | 20 ft. | 0.718 | 6.05 | 1—8.4 |
| 13a ... | Modification of 5 | 8 | 20 ft. | 0.026* | 0.058* | 1—9.3 |
| 13b ... | | | | 0.66 | 6.20 | |
| 14a ... | Different make of blasting gelatine | 6 | 36 ft. | 0.035* | 0.25* | |
| 14b ... | | | | 0.467 | 4.00 | 1—8.5 |

a and asterisks indicate before blasting. b after blasting.

Table I deals with a series of experiments which are almost self explanatory, but in calculating the ratio of CO to CO₂, the figures of which appear in the last column, I have made no correction for the amounts present in the gases before the blast, though in some of the cases it is evident that they would materially affect the ratio. My reason for not doing so is that I do not think there are sufficient data to go upon. The one point which is established beyond the shadow of a doubt is, that carbon monoxide is always formed in large, and even dangerous quantity. The presence of the large percentage of carbonic acid calls for no remark, and where larger quantities than the usual are indicated, the natural conclusion is that the sample has been obtained in a concentrated form. Strange to say, no trace of nitric peroxide was found in any of the samples, though we would not be justified in asserting that it was not formed. I think myself it must have been formed in every case.

On the question of tamping, divergent opinions are held. I believe that good clay is infinitely better than

sand, and if trouble were taken to procure it and to make it up into proper cartridges much better results would be obtained. The experiments given in Table II are only of a preliminary nature, but they are interesting as indicating a decided improvement in favor of dagga, which, as you know, is at least an approximation to clay. The tamping cartridges were made up in the usual way with the dagga dry, but they were used damp, which makes it somewhat sticky or adhesive.

TABLE II. INFLUENCE OF TAMPING.

| No. of experiment. | Tamping. | Distance from face. | Gas Composition. | | Ratio of CO to CO ₂ |
|--------------------|--------------------------------|---------------------|------------------|-------------------|--------------------------------|
| | | | CO. % | CO ₂ % | |
| 15a | Dagga cartridges..... | 47 ft. | 0.356* | 0.049* | 1—7.93 |
| 15b | | | 4.60 | 0.58 | |
| 16a | Ordinary sand cartridges | 47 ft. | 0.258* | 0.050* | 1—6.5 |
| 16b | | | 1.84 | 0.28 | |

a and asterisks indicate before blasting.
b indicates after blasting.
Ordinary blasting gelatine used with No. 8 detonators.

In a later paper I propose to deal with the subject of blasting by electricity, and the figures given in Table III have reference only to a phase of that question. We all know that comparatively large amounts of carbon monoxide are produced from the burning fuse, and the amount used for the blasting of a round is from 72 to 96 ft. The cut is generally drilled so as to make holes converge at the bottom, and this in practice means that the cut comes away at one blast. I had an idea that firing by electricity, which ensured the simultaneous detonation of all the shots, would give better results, and the figures of this table certainly indicate a little improvement. Against this is, of course, the production of carbon monoxide from the burning of the fuse, but from other experiments it does not appear that the amount from this source could seriously vitiate the results given. In No. 10 only three holes were fired, as against four in all the others.

TABLE III. RESULTS OBTAINED FROM BLASTING CUTS.

| No. of experiment. | Explosive. | Detonator | Distance from face. | Gas Composition. | | Ratio of CO to CO ₂ |
|--------------------|-------------------------------|--------------|---------------------|------------------|-------------------|--------------------------------|
| | | | | CO. % | CO ₂ % | |
| 8a | Blasting gelatine 3 weeks old | 8 | 12 ft. | 0.014* | 0.35* | |
| 8b | | | | 0.195 | 1.63 | 1—8 |
| 9b | Blasting gelatine 3 weeks old | elec dets | 27 ft. | 0.208 | 2.03 | 1—9.7 |
| 10a | Blasting gelatine 3 mo. old | elec dets | 27 ft. | 0.017* | 0.23* | |
| 10b | | | | 0.205 | 1.72 | 1—8.4 |
| 11b | Blasting gelatine 3 mo. old | 8 | 27 ft. | 0.22 | 1.71 | 1—7.7 |

a and asterisks indicate before blasting.
b indicates after blasting.

The results of the foregoing experiments were so surprising and unlooked for that I next decided to try gelignite, which is used for development at some mines. Gelignite may be described as a low-grade blasting gelatine to which is added organic matter in the form of wood pulp and nitrate, so proportioned that the oxygen from the nitrate is capable of oxidizing all the organic matter. Whether this oxidation is complete or incomplete has never been determined in practice, but judging from the analogy of ordinary black powder one would be safe in assuming that the combustion would not be complete.

According to theory, 12b and 13b should have furnished free oxygen, particularly 13b, but they do not. This is hardly surprising in view of the fact that the results obtained all through deviate so much from

the theoretical. I would again direct attention to the high CO to CO₂ ratio of 13b, the highest so far found. It is stated in another way in Table I, but does not show up quite so high there, though the difference is not great.

TABLE IIIa.

| Gellignite. | Before blast. | After blast. |
|-------------------------|---------------|--------------|
| Oxygen | 20.310 | 17.96 |
| Nitrogen | 79.300 | 74.52 |
| Hydrogen | nil. | 0.11 |
| Carbon monoxide | 0.028 | 1.23 |
| Carbon dioxide | 0.362 | 6.18 |
| Olefines | nil. | nil. |
| Oxide of nitrogen | nil. | nil. |
| | 100.000 | 100.00 |

Proportion of CO to CO₂, 1 to 4.9.

The examination of every-day mine gases with regard to their vitiation is outside the scope of this paper, and no useful purpose will be served by directing attention to particularly bad samples. I can say in general terms that some of the places underground were unfit for human beings to work in, and it was wonderful how they managed to do so. On the other hand, some of the analyses indicated a purity almost equal to the atmosphere at Sea Point, but while gladly admitting this, I wish to make it clear that I think the subject of ventilation is not receiving that amount of consideration which it ought to do in the light of the advances which are being made in other directions. I believe that few of those responsible for practical operations in the mining industry realize the importance of the subject, and what economic advantages improved ventilation would bring in its train.

The conclusions at which I have arrived may be summarized as follows:

(1) Carbon monoxide is produced in large quantities on the detonation of blasting gelatine, under the ordinary conditions of practice.

(2) The so-called neutralizers or anti-fume mixtures do not appear to have any influence one way or another.

(3) Clay-tamping seems to give better results than ordinary sand-tamping.

(4) Freshly made blasting-gelatine gives no better results than that which is three months old.

(5) With an age limit of three months a No. 6 detonator seems to answer as well as a No. 8.

(6) Blasting-gelatine of the nature of 13b seems to give better results than the ordinary blasting-gelatine.

(7) Firing by electricity seems to give slightly better results than ordinary time-fuse.

(8) The ordinary quantity of fuse used vitiates the mine atmosphere to a very large extent.

When holes are required deeper than 6 or 8 ft. it is necessary to use either a hand or power-driven churn-drill, because effective work beyond that depth with hand-hammer and drill is impossible, owing to the fact that a long drill 'takes up' the force of the blow with the hammer. As churn-drill holes are made by churning the drill up and down in the hole, the depth that can be thus reached is limited by the available power for lifting the drill-tools. Holes over 1000 ft. deep are often made with a steam-driven churn-drill.

MINERAL DEPOSITS IN TREBIZOND.

The Province of Trebizond, lying along the southern shore of the Black Sea, in Asiatic Turkey, holds brilliant promise for a flourishing universal industry. It was described in a general way by Leon Dominian in an article, 'Mines and Mining in Turkey', published in the MINING AND SCIENTIFIC PRESS, June 12, 1909. The accompanying map gives more detail concerning the region, its division into districts, and the distribution of mines. In the district of Surmene all the deposits represented contain copper with the exception of those numbered 1 and 4, which yield manganese. In Yomoura all the mines are of copper, No. 1 yielding a complex ore, containing zinc, and No. 6 showing considerable amounts of arsenic. Both No. 1 and 6 are basic ores with a large excess of iron. In the district of Djevislik silver occurs with the copper in mines No. 1, 3, and 10, and No. 7 and 12 are highly basic copper ores, with coal in close proximity to No. 7. In mines No. 10, 13, and 16 lead is also present. Lead is associated with the copper ores in Kalanema-Dere Fol

up docks when the traffic warrants the outlay. The first section of the railway of 105 kilometres (65 miles) was completed and ready for traffic in July of the present year, and opens one of the richest and most populous districts in the country, whence the products should find ready markets, not only on the Coast but in the United States and Europe. In addition to the mineral wealth of the district the whole route tapped by the Chimbote-Recuay railway is very rich in minerals, principally copper, silver, and gold, and while many mines are already operating, the majority are waiting for the railway.

COPPER IN JAMAICA.

Recent explorations have been made in Jamaica, mainly in the Clarendon hills, exposing large deposits of copper silicate (chrysocolla), copper pyrites, cuprite, bornite, malachite and azurite, copperglance, and other copper ores, carrying silver and gold. The existence of copper in Jamaica was evidently known to the Spaniards several centuries ago, as the name of one of the large rivers, Rio Cobre (Copper river) indicates. When the English took

Province of Trebizond, Asia Minor.

in mines No. 1, 2, and 4; No. 3 is a maganese mine. The district of Charly yields copper from all the known mines, silver being found in notable quantities in No. 2, 3, and 10. Tireboli also possesses extensive copper deposits, with lead in No. 3, 5, and 6. Manganese in workable amount exists at No. 1 in Kerassund, which is held by a 'firman' or concession for 99 years. No. 2 is a silver-lead property, No. 3 is a silver-lead mine containing much antimony, No. 4 is a copper-lead deposit, while the others are copper mines, with coal adjacent to No. 10. An exceedingly complex mixture of copper, zinc, lead, and antimony is found at No. 11 in this province. In Ordou argentiferous lead-copper ore occurs at No. 2; lead and copper at No. 3; lead alone at No. 5; and copper at all the others, with the exception of No. 8, which is a coal mine, and No. 1, which is a hot spring called Yumre, held by Faik Pasha on a 55-year concession.

possession of the island in the seventeenth century they devoted their attention to agricultural pursuits which yielded immense profits. It is of record, however, that in the year 1854 samples of copper ore were sent from the island to the Revere Copper Mining Co., of Boston and smelted, producing about 24% metallic copper.

A number of Boston men obtained a lease in 1906 of no less than 2267 acres of land in the Clarendon hills, nearly 4 square miles, with an option of purchase within a few years, and since then they have been spending their own capital prospecting and developing the deposits. Rapid progress has been made, and these recent copper developments give promise of great economic value and importance to Jamaica in an entirely new and hitherto undeveloped field. There were about 75 laborers at work on the mines recently, and 62 openings had been made. From more than 40 of these, ore has been taken showing profitable copper content, all carrying silver and gold. The climate is such that work can be carried on throughout the entire year. More than 1200 ft. of tunnels had been made up to March last. The mining will be done entirely through tunnels; no pumping of water or hoisting of ore will be necessary, hence it will be comparatively inexpensive.—*Engineering Magazine.*

One of the most important enterprises in the development of Peru, now being carried out, is the construction of the railway for the Chimbote Coal & Harbor Syndicate, Ltd., which will run from Chimbote to Recuay, a distance of 168 miles. This syndicate also possesses a mole which is under reconstruction, also extensive coalfields, and is prepared to fit

GAS ENGINES FOR MINING PURPOSES.

Written for the MINING AND SCIENTIFIC PRESS
By A. S. ATKINSON.

The electrification of mines has greatly simplified operations in recent years, and has also reduced the fire and explosion hazard, and where current can be obtained from some near-by hydro-electric plant it is undoubtedly the cheapest and most efficient method of operating the various machines and apparatus. Almost every phase of work about a mine can advantageously use electricity, including hoisting, signaling, lighting, driving, ventilation, hauling and tramming, firing of shots, surface-work, and ore-treatment.

Comparatively few mines are so situated that they can draw upon hydro-electric power-plants for their current, and the cost of power-development of any kind becomes to them of more importance than the question of form of transmission. It is in such mines that large gas-engines and more recently large suction producer-gas plants have entered as new factors. Mining operators a few years ago were prejudiced against gas-engines for mining purposes owing to their general unreliability. Through the more recent development and perfection of gas-engines mine owners have seriously taken up the question of using them. There is no disputing the remarkable achievements of gas-engines in other fields.

Gas-engines of large capacity reached their first development in Europe where the fuel problem is more acute than in this country, and likewise the suction gas-producer was more generally adopted there than in the United States. One must frequently look to European mines for data concerning the development of new power-producers. Economy of fuel-consumption is of primary importance there. Frequently the European mines could be operated upon the waste found around American coal mines. One of the most significant experiments with gas-engines for mining operations has been conducted at the Powell Duffryn Collieries in South Wales, and the results are not without their lesson. In the South Wales collieries the power-equipment consists of two large gas-engines, one of 1200 hp. and the other of 2400, which is one of the largest gas-engines ever installed in a mine of any description. These gas-engines are coupled to alternators for supplying three-phase current to different parts of the mines. The big gas-engines are started by compressed air which is stored in tanks at a pressure of 300 lb. per square inch. This makes attendance cheap and simple. Under ordinary circumstances, the engine-room staff consists only of one switchboard attendant, and a driver and cleaner for each engine. The engines are run almost continuously without stop from one week's end to another, with the exception of Sundays when they are cleaned and overhauled. Any accumulation of carbonized oil on the pistons or cylinder-covers is then removed and the plant oiled and cleaned thoroughly. The cooling-water for the engine-jackets is stored in a reservoir about 80 ft. above the level of the engine-floor, and this gravity-feed always insures a steady and uniform supply. There is a large amount of hydrogen in the

gas, and this tends to cause pre-ignition at a comparatively low pressure, and the engines are built to operate under a compression of gas ranging from 90 to 105 lb. In spite of this, however, the thermal efficiency is quite high and very satisfactory. In tests made with the gas-engines operating under full load it was found that they were using 12,300 to 13,000 British thermal units, and developing a full load capacity under all ordinary conditions.

Since the installation of these gas-engines in the collieries there has been no shut-down, and only one slight interruption of a few hours to one engine, which amply testifies to the reliability of the equipment. Before the gas-engines were installed the mine equipment for power-generation was entirely of steam, and the cost was from 10 to 20% higher than under the present method. The saving is obtained as much in the cheaper cost of attendance as in the consumption of fuel. Plans are now being matured for installing two more engines of large capacity in the collieries. This gas-engine plant for mining operations is not so up-to-date as others installed in this country and in England, but it is such an improvement over the older equipment that it represents a distinct advance. The suction gas-producer is looked upon by many mining engineers as ideal. The development of the suction gas-producer is a matter of comparatively recent history. Its growth has been extraordinary, and its adaptation to many kinds of work is a feature of mining and manufacturing industries. While the producer has reached a high stage of efficiency for operation on fine grades of anthracite coal, the more important question of adapting it to burning various forms of bituminous coals is more recent. The requirements of such a plant are exacting. In the first place there is demanded a producer capable of continuous and uninterrupted operation. Reliability of the plant is of first importance. It should also produce a gas free from tar, and operating at such temperatures as would avoid troublesome clinker formation. A suction producer that would possess these virtues, and at the same time be so simple and easy of operation that comparatively little skill on the part of the operator would be required, would prove a boon to mines. Of course the gas produced would have to be suited to high-compression engines.

It has not been easy to secure a suction producer that would possess all of these qualifications, and the improvements have come about gradually, if not quickly. Today suction gas-producers that approximate these results are built both in this country and in Europe, and the satisfaction they give is their best recommendation.

As an illustration of the early use of a suction gas-producer in mines attention might be called to the gas plant at the Threlkeld mines at Cumberland, England, where operations have been going on for several years. This plant has a producer modified to suit local conditions and the fuel most abundant, which is Scotch anthracite, of pea size. There are two gas generators, and the engines are directly connected by a flexible coupling to 60-kw. direct-current generating sets that run in parallel. The fuel

is fed into the producer by means of a storage feeder and hopper so that a large body of incandescent coal is supplied below and a fresh supply held above ready for use and warmed to a high temperature at all times. This prevents any sudden cooling of the fire by fresh charges.

One of the difficulties encountered with producers of all kinds is efficient working under light loads. The loss of efficiency when working under light loads was one of the weak points of the early producer plants, but this has been overcome. If the plant works for some time under light loads, the fire is apt to decline to such a point that a good quality of gas fails of generation. The suction is reduced to such a point that there is not sufficient fresh air drawn in to keep the fire active without auxiliary equipment. This is overcome in modern producers by auxiliary blowing apparatus or by a by-pass fitted between the gas-pipe and the mixing chamber, so that an additional small supply of air is drawn in to suit the light-load operations. In nearly all mines the gas plant must run on a light load during the night, usually for lighting and pumping purposes alone, and the necessity of having an efficient plant that will operate economically under such conditions is important. At the Threlkeld mines, the fuel consumption averages one pound of anthracite coal burned per horse-power hour, and compared with a steam-plant this is economical. Also the cost of attendance is considerably lower than for a steam equipment. Again the stand-by loss is unusually low, and compares favorably with a steam-engine. At the Threlkeld mines a number of tests have been made to secure reliable data concerning the use of the suction gas-producer for winding, pumping, lighting, and ventilating by electricity. These experiments were made within a year after the initial installation, and when the plant had been well keyed up and had proved reliable in operation. The results of these tests showed that the fuel per hour used for developing each kilowatt-hour amount to only 1.50 lb., with an average dynamo-load of 40.1 kilowatt-hours. In these tests the efficiency of the dynamo at two-thirds load averaged 85%. The calorific value of the coal used was 13,556 British thermal units.

One of the newest suction producer-gas plants developed in this country by American manufacturers for working on different grades of bituminous coals for mine purposes shows results that are of even more value to the mining industry. Tests have been made with this producer with South American lignite coal, Colorado lignite, Texas lignite, Massachusetts meadow peat, and Pittsburg run-of-mine coal. All of these low-grade fuels have given excellent results in the producer. The Pittsburg run-of-mine coal showed an economy of 1.1 lb. per brake horse-power hour in a 24-hour operation, and the lignites averaged an economy of 1.6 lb. for continuous service. The efficiency of this producer in the tests did not vary more than 10% from full to no load, and approximated 77.5 on total heat-value, or 71.5% on effective power-value basis. The average samples of gas taken from the engine showed a heat value of about 115 British thermal units effective power-

value. A high-grade gas was not desired, as the compression was moderately low, although a high-grade gas could have been obtained by admitting more oxygen.

The perfection of electrical winding will greatly simplify the application of electricity for general mine use, and it is by the introduction of the suction gas-producer that collieries and metal mines will receive the full benefit of this improvement. Electricity for general mine uses has demonstrated its efficiency and reliability. But it is the cost of securing the current that concerns most mine owners. Where cheap hydro-electric power can be obtained the problem is easy, but for the hundreds of mines not so favorably situated the suction gas-producer promises much. In many inaccessible districts it simplifies operations and increases the efficiency, and it may often prove the determining factor between success and failure.

The Empresa de Navegación Louis Gieseken and the Magdalena River Steamboat Co., with respective fleets of approximately 21 and 15 stern-wheel steamboats and various smaller craft, such as lighters and barges, have for some time controlled the traffic of the Magdalena river, Colombia. They also carry the mails, with Government subsidies of \$1000 gold per voyage, between Barranquilla and La Dorada or Puerto Berrio and return, there being five mail steamboats per month. The new Compañía Antioqueña de Transportes will enjoy the same rights, except the mail subsidy. Its capital is \$300,000 gold, 90% of which has been subscribed in Medellín, the remaining 10% being divided among residents of Bogotá, Barranquilla, and Manizales. Four years ago the company was engaged in river traffic, with two boats, and is resuming operations with promising prospects. Two stern-wheel boats of the type commonly used on the Mississippi, with electric lights and other modern conveniences and equipment, were ordered last October from James Rees & Sons Co., Pittsburg, Pennsylvania. The first steamboat arrived about the middle of April. It is claimed that they are bigger and better equipped for both freight and passenger service than any boats now plying on the river. They will be called the *Medellín* and *Caldas*, are of 380 tons each, 170 ft. long, 33 ft. beam, with 4 ft. 6 in. depth of hold, and will draw approximately 4 ft. of water when carrying full cargo. The company possesses excellent facilities at Barranquilla for handling and storing cargo, a switch from the local railway having been built into their sheds at the pier so that cargo can thus be transferred from the river steamers directly to the cars and thence conveyed, without further handling, to the ocean steamers at Puerto Colombia, and vice versa. As the company is practically owned by citizens of the Department of Antioquia, generally considered the greatest ore-producing region of Colombia, it may naturally be expected to secure a large proportion of the ore and machinery shipments of that district, all of which should result favorably to the American mining men in the interior, as well as to the manufacturers of mining machinery at home, as to both freight rates and improved service.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

GENERAL LECTURES ON ELECTRICAL ENGINEERING. By Charles Proteus Steinmetz. 8vo., pp. 284; Ill. by diagrams. Robson & Adey, Schenectady, N. Y., 1908. Price \$2.

Any utterance by the wizard electrician of Schenectady must command world-wide attention. Mr. Steinmetz was well named Proteus; he has rapidly taken every part in the shifting play of electrical progress. Like all great men, he displays the characteristic of extreme simplicity, which is the same as saying that his view is straight and clear, so that his account of what he sees is lucid, plain, direct, and logical. He makes no bid for favor by putting on the outer garments of complexity. It is a delight to read these lectures. Criticism is superfluous in connection with a book by a past-master of an art. Errors, and personal convictions there may be, but the suggestiveness of the volume is the reason for reading it; the dull practical details can be had in a hundred books, but the pregnant hints come only from such as this. As an example, in discussing high-tension transmission, he refers thus to lightning discharge: "The illumination given by a brilliant lightning flash is about of the same magnitude as good artificial illumination, perhaps one-foot candle, since at night time in a well lighted room, the light of a lightning flash is still quite appreciable. Estimating roughly one watt per candle foot, a lightning flash illuminating a space of two miles square or 10⁸ square feet, with one-foot candle would consume 10⁸ watts, and as this is the illumination as averaged by the human eye over 0.1 seconds, the energy is 10⁷ watt-seconds, or 10,000-kw. seconds. The energy of a large lightning flash, estimated from its light, would thus be of the magnitude of 10,000-kw. seconds. This value, while considerable when expressed in electric quantities, is by no means so very great; reduced to heat measure, it only equals the latent heat of evaporation or condensation of about 9 lb. of water."

STEAM POWER PLANT PIPING SYSTEMS. THEIR DESIGN, INSTALLATION, AND MAINTENANCE. By William L. Morris. 8vo. Pp. 506, Ill., Index. McGraw-Hill Book Co., New York, 1909. Price \$5.

This work is a systematic discussion of the problems arising in the design of piping systems in connection with high-grade steam-power installations of the present time. It enters into the minutest detail of economic questions involved, in designs leading to higher efficiency in service, and in the practical questions of plan and installation. The book contains 32 chapters, all well illustrated. As an example of its scope we present a few of the headings: Piping Diagrams; Piping Systems; Live-Steam Drips; Blow-Off and Exhaust Piping; Air and Oiling Systems; Oil and Water-Purifying Systems; and Details, in separate chapters on live-steam, vacuum-exhaust, atmospheric exhaust, boiler feed, feed and fire-pump suction, heater-water supply, low-pressure water, condenser cooling-water, etc. It is a book of great practical value, and should be in the hands of every designer of steam-power plants, and it will prove suggestive in the direction of improvement for operating plants.

ESTADISTICA MINERA DE CHILE, 1906-07. Vol. III. Large 8vo. Pp. 518. Ill., Index. Prepared for the Chilean Government by the Sociedad Nacional de Minería, under the direction of Guillermo Yunge. Santiago de Chile, 1909.

This work is of greater value than any preceding volume, and practically sets out as if those did not exist. It is the most comprehensive statement available concerning the minerals and geology of the Chilean Republic. It gives a resumé of the topographic and geologic features of the country, the climate and productions, ports and means of communication to interior points, mail and telegraphic service, and the mining law. It then deals in detail with special products in separate chapters, one being given to coal, another to natural salts, and one to guanos and sul-

phur. The book contains 24 chapters in all, and it will suffice to point out that excellent descriptions in great detail, are presented of the gold occurrences and their exploration, of silver, copper, manganese, cobalt, lead, and others, together with an account of the geology of the districts referred to. There is an account of petroleum occurrences, and of borates. Special chapters, well illustrated, deal with the Braden Copper Co., and the great iron and steel works being installed by Schneider & Co. at Corral, under the title Cia. Siderúrgica Francesa. There is also an admirable summary of what is known of the mineral deposits of the Territorio de Magallanes, a region that is attracting world-wide interest because of its gold, copper, and coal. An important chapter is one by Lorenzo Sundt, entitled 'The Present State of Knowledge Concerning the Geology of Chile'. The book is excellently written and well gotten up, and will be of great value to anyone interested in Chile, who can read Spanish.

GAS-ENGINE THEORY AND DESIGN. By A. C. Mehrtens. Large 12mo., pp. 261. Ill., Index. John Wiley & Sons, New York. 1909. Price \$2.50.

The gas-engine is so rapidly taking a leading position as a prime mover, not only for small units, but for power-generation on a large scale, that every work on the subject is of interest; every book offers new hints which are helpful and suggestive. The volume now presented by Mr. Mehrtens is particularly well done, and should prove of great value to all students of gas-engine construction. More than this, no user of gas-engines can fail to better equip himself for the management of such machines by studying the problems involved in their design. The book is elementary but scientific, presupposing a knowledge of elementary mechanics. The work is accompanied with a valuable set of reference tables, covering physical properties of materials, petroleum distillates, properties of fuel gases, volumes and specific heats of gases, efficiencies at different altitudes, heat and power-units, and volume, pressure, and temperature curves.

STRENGTH OF MATERIAL. AN ELEMENTARY STUDY PREPARED FOR THE USE OF MIDSHIPMEN AT THE UNITED STATES NAVAL ACADEMY. By H. E. Smith. 2d. Ed., revised. Small 8vo. Pp. 170; Ill. John Wiley & Sons, New York. 1909. Price \$1.25.

The neat presentation of the elements of the study of strength of materials made in this volume is well known. The fact that it was designed for use at the Naval Academy does not imply that its leaning is toward naval construction. The author might properly have omitted mention of its specific purpose, which has nothing to do with the matter included. It is simply a brief review of the subject, for engineering students who have had the calculus.

NINTH ANNUAL REPORT OF THE STATE GEOLOGIST [Michigan]. By Alfred C. Lane. Pp. 28. Lansing, 1908.

This, the administrative report for 1907, contains a general account of the work of the Survey and is accompanied by separate reports on 'Foundry Sands' by Heinrich Reis and J. A. Rosen; 'Summary of the Surface Geology of Michigan', by A. C. Lane; and a 'Biological Survey of Walnut Lake', by T. L. Hankinson.

THE TOTAL production of coal in the United States in 1908, according to the statement just issued by E. W. Parker, of the United States Geological Survey, was 415,842,698 short tons, having a spot value of \$532,314,117. In 1907, which was the record year, the production amounted to 480,363,424 short tons, valued at \$614,798,898. The total production in 1908, it will be seen, decreased 64,520,726 short tons, or 13.43% in quantity, and \$82,484,781, or 13.42% in value. The production of bituminous coal in 1908 amounted to 332,573,944 short tons with a value of \$374,135,262. In 1907, the production of bituminous amounted to 394,759,112 short tons valued at \$451,214,842. The anthracite production in 1908 reached 74,347,102 long tons, with a spot value of \$158,178,849. In 1907 the anthracite production amounted to 76,432,421 long tons valued at \$163,584,056.

MINING AND METALLURGICAL PATENTS.

DRILLING-MACHINE.—No. 917,484. James Petrie, Ross-land, British Columbia.

In mechanism of the character described, the combination with a cylinder, of a reciprocatory piston operating therein and having a piston rod projecting from one end, a bushing surrounding the projecting portion of the rod and closing the end of the cylinder, said bushing comprising separate longitudinal sections having a plurality of annular packing-receiving grooves on its interior face, the exterior face of the bushing being continuous, unbroken, and uniformly tapered from its point of largest diameter to its outer end, said point of greatest diameter being located adjacent to the cylinder, a shell surrounding the bushing and having a continuously and uniformly tapered bore corresponding to the taper of the bushing and receiving the same, and resilient means entirely out of engagement with the bushing acting to continuously force the shell inwardly toward the cylinder to force the sections of the bushing together and to hold the bushing in place on the end of the cylinder.

SAFETY-CATCH FOR MINE SKIPS AND CAGES, HOISTS, AND THE LIKE.—No. 917,332. Victor H. Malston, Johannesburg, Transvaal.

In a safety catch for hoisting apparatus, the combination with the vehicle and guides thereof of a pair of shafts revoluble in converging guiding slots in the sides of the vehicle, friction rollers on the ends of the shafts for engaging the sides of the guides, converging racks fixed to the vehicle, and pinions on the ends of the shafts engaging the racks, a member by which the vehicle is supported and flexible connections between said member and the afore-said shafts, as set forth.

METALLURGY OF STEEL.—No. 918,382. William S. Simpson and Howard Oviatt, London, England.

An improvement in the art of manufacturing steel directly from ore which consists in associating a suitable percentage of finely ground graphite with the ore in a fine state of division and adding thereto a reducing carbonaceous substance containing water, and then heating the ore charge thus prepared to effect its reduction and the carburization of the metal.
